Just wondering how a few mils of PVC insulation would effect the permittivity of a couple of 12 guage wires spaced a couple of inches apart.

I tried one a few years ago to use when I go camping. Having a hot
shield did prove to be problematic. This also got it retired to the
junk bin. My favorite antenna for camping is an NVIS antenna that
takes the form of a wire Yagi-Uda aimed skyward. All I need to put it

up is a couple of suitably spaced trees.

By "mils", do you mean thousands of an inch? (The rest of your dimensions
are imperial.)

I doubt it would make much difference

The easiest way I know of to assess the effect of the mixed dielectric
environment, is to measure the velocity factor, and use that to infer an
equivalent permittivity (as I noted in my earlier post).

Owen

4556. VHF relays and VHF SWR meter for sale

Newsgroup: rec.radio.amateur.antenna
Date: 2010-10-29 03:40:09 UTC
From: Henry <wa0goz@arrl.net>
Message-ID: <iadfmjmte2@news.eternal-september.org>
Source record: 6906

I have two NEC 536300 relays for sale. The specs are:

50 ohms input and output
150 Watts to 470 MHz
VSWR 1.25:1
Crosstalk 40 dB
12 VDC coil
Shown in August 1965 VHFer if you still have it. I don't.

They can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz click on photo to enlarge it.

I'm asking $10 each plus shipping.
==========
I have a Heath HM-2102 VHF SWR meter 50-160 MHz
0-25 and 0-250 watts. Very good condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz click on photo to enlarge it.

the diode causes an imbalance, not the transmitter. it can be either
direction depending on the orientation of the diode... how does your
electron flowing explain that?

You must do the next progress. The simplest radio is like a photocell. There
are the two copper plate with the semiconductor between. Electrons always
flow from the side exposed to light to side in shadow. Never in opposite.
One plate is as an antenna and the other as the chassis.
Do you agree?

There is an alternate electric field between the antenna and earth.

Electrons will move down through the earphones and up through the diode.

This is where I got the idea, Lots of other info on various designs
just by googling NVIS antenna. I usually do 40M as the antenna for 75M
is often impractical to put up but I have one just in case. There is
one place I could probably put up one for 75 over a pond.

Dear John: As others have said - expect a lot of coupling. However, even a second read did not disclose what you wish to place on a 40 foot tower - or if you expect to use the new tower as the end for one or more wires.

Clearly the example of a 3 element 40 meter beam at 40 feet makes no sense.

You should put the meter in series with the diode or the earphone, not
in series with the antenna or the earth.

In the diode and in the earphones you have direct current that the meter
will measure, in the connection to the antenna and the earth, you have
radio frequencies that the meter will not measure correctly.

4571. 160m Vertical Questionas

Newsgroup: rec.radio.amateur.antenna
Date: 2010-10-30 11:50:25 UTC
From: Dave WB4IUY <support@scootworks.com>
Message-ID: <7f09a384-c4bc-43b3-a375-191e4cca5cce@v20g2000yqb.googlegroups.com>
Source record: 6921

I have a 105' tower with a cluster of yagi's on top. There are various fixed-direction yagi's bolted to it, along it's height. There are 17 runs of feedline that come from the tower to the shack. I've always wanted to install something vertical for 160m use in the quiet winter months. The 1st and 2nd layer of guy wires are un-insulated from ground/tower. The top guy wires are broken into full 40m sloping dipoles and are remotely switched. Due to all of the other rigs running at the same time and the amount of feedline entering the shack, I don't think I want to shunt feed the tower for fear of getting loads of RF in the shack (had a friend who tried this and was never able to fix the problem with RF in the shack). Here's my question:

- Can I use insulative side-mount brackets and string a vertical up the side of the tower, seprated from the tower by a few feet, and get any kind of decent vertical antenna performance out of this? I was thinking of maybe 5' off the side of the tower, running a wire up to 105', then shoot the other 30 or so feet of wire off and fold it back down and outward at 45 degrees or so. Feed it at the bottom, and install a ground field aound the base of the tower.

I realize there will be some coupling to the tower, but don't have any way (or know how) to model this. Can anyone help with a model to determine approximately how much I'll have to compensate wire length for couplng and top foldback? Have any of you done this before?

Thanks,
ave WB4IUY

a simpler method is to put an insulator at the top of the tower and
run up at an angle so its 20' or so away from the tower at the
ground. the further away from the base of the tower the less coupling
and the more wire there will be going up... and the more art will like
it!

Thanks for your advice! The more views I get, the less likely it is
for me to make bad decisions.

Here is where my thinking is now:

I need to put the second tower wherever it will be most useful to my
purposes. The existing vertical array and its radials are expendable.
It can be reconstructed if desired at another time. I believe it has
served my purpose and it is time to move on. Installing a tower is not
a trivial matter and the decisions should be made to take advantage of
the opportunities it provides.

My interests are a little different than most Hams. I enjoy studying
more than operating. Building and using antennas is an important part
of the hobby (addiction?) to me. When I made the retirement move to
this location I made certain that I would be able to pursue that path.
I have enough real estate, wife does not care what I choose to do with
the hobby, and the neighbors are indifferent as well! I consider all
the antennas to be temporary and everything must be accessible. Twice
this past week I have lowered the existing Tribander to 25 feet
because of weather forecasts. Change is the rule rather than the
exception!

If I encounter excessive interaction I will just consider it another
condition to explore. I started out with the idea that this would be a
30 foot VHF-UHF structure but it appears that I can reach a little
higher and stronger than that.

I will keep the options open as best I can to provide a second
structure that lends itself to further experiments.

At least that is what I am thinking today...

Stokes drift and Tesla's electric waves are reality.

Heaviside's compilations (TEM) are funny.

Hello All

I have the above Beam using a switch box Dosy A-SW-4 Vert-Horz-Aux-Vert/Horz and my coax Belden 9913U. My question is does anybody know how to setup Circular Polarization when the switch is on the Vert/Horz. I have one length each of 9913U coming from Vert and from Horz.

All help is greatly appreciated
Thankyou
Terry

EZNEC will do that. A quick look says that it will work just fine.
There's not much difference in feeding the tower and feeding a wire
parallel to the tower.

And yet they have nothing to do with EM waves.

Sorry, I forgot. You don't believe in EM waves.

What's it like to live in a fantasy world?

give me a number... i have 6 transmitters running 1500w rf output each
into 50 ohm antennas. There is one ground cable to all the stations,
how much dc current should i measure in that ground cable? show work,
extra points for neatness.

Everybody know that Tesla coil is pumping the earth's charge (pulsatory
flow). The same do yours 6 transmitters.

Stop writing and try to detect it in your ground cable. In the Warshaw LW
mast it would be easy. But it collapsed.

Browsing thru E bay I came across a 1kw
antenna tuner for sale from Cyprus.Now in my younger days I got hold
of one of these and intended to salvage a Icom AH2 to somehow make it
remote since I use Icom radios. After all there are only three motors
that have to be driven! Now I am retired I pulled my old one from
storage after seeing the same on E bay. Question is are there any
kits, salvage ideas out there that would get me going on this long
lost project?
I have never used a external tuner but this seems like a realistic
project to play with.
Of course if there is a unit out there that I can salvage a controller
that is all the better. There are very good photos of this particular
tuner on E bay but like mine it has no controller! I suppose I could
feed a 10 watt signal to it and control the motors by hand to tune but
I do like the idea of automation.
Regards
Art

i have tried, i can't detect it... how much does your theory say
should be there so i know if i am not reading sensitive enough meter.
theories that can't make measureable predictions are not very useful.

I knew that was coming!
My antenna project is finished and active on the grass Now winter is
coming I need another project. I wanted the antenna to pan up and down
for best angle automatically but I am short on ideas. So seeing the
tuner on Ebay reminded me of a project that got away. The antenna has
only been tested down to top band as I am not equipted to go down
lower and the mfj only goes up to 170. I suppose I can take the tuner
to a hamfest but it has been a few years since I went to one. I am
using a window
wiper motor for the up and down so it would be nice to make that
automatic if more gain is available.

If you get one put together let me know how it works for you . My
operation have been very sporatic and I really cant compare it well
with anyting. I would think operation would be best when both stations
are using NVIS antennas but I have yet to communicate with someone who
was doing the same. I have made contacts on this antenna when another
antenna an 18ft vertical was just dead quiet, Location was in a
campsite in a valley near Boone NC.

OK here is what I know about it. It was a pyramid shaped antenna approximately 20 ft on a side at the base. The antenna was supported by a central mast from the apex of the pyramid and the base of the antenna was suspended about 3 or 4 ft off the ground. Corners of the base of the pyramid were tied off to tent stakes with nylon rope. It was used for HF communication in the range of 4 to 30 Mhz and I the the nomenclature for it was OGTHAGONAL ANTENNA. Thats as much info as I have if anyone could add more I would appreciate it. Is this an NVIS antenna? Manuals would be great. Last time I saw one in use it was being used for HF SSB Air to Ground communication.

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

should be there so i know if i am not reading sensitive enough meter.
theories that can't make measureable predictions are not very useful.

You have 1500W, LW transmitters 1500kW. But the biggest is the Sun.
Planets have the excess of electrons. Receiver antennas close to transmitter
should also have.
But everywhere are an exeptions (materials dependent). Like with the Hall
effect.

In a ground cable is the pulsatory flow of electrons.
A current meter has the resistor and voltmeter. Try an osciloscop instead of
voltmeter. The voltage should not be symmetric. But I am not an expert.

The bottom antenna on the first page of <http://csantennas.com/HF-antenna-systems.htm> is often configured as you describe. The two dipoles are attached to the same center insulator / connector assembly and run at ninety degrees to each other. Forward Air Controllers would use them to direct tactical air support. I own one of these that I acquired in a trade. When I was a zoomy they would be set up exactly as you describe during field communications exercises but I don't know if the intention was to use them as NVIS antennas or not. There was quite a lot of google hits on the spelling that Bill suggested. vis Orthogonal Antenna.

Again a school physics.
The Sun attracts all solids body. They are reworked into plasma.
Oscillations is a by product.

Not only planets. Everything has excess of electrons.

It isn't the tuner hardware that is going to be a problem, as much as
designing the tuning algorithm that drives the hardware. Mark Johnson
did a very good job, reverse engineering the stuff that Bill Shield
brought west from Motorola Military back in the 70's for the SEA
Autotuners. SGC copied the SEA Firmware & Design enbank, for their
stuff. The best stuff, was the stuff Collins did for their Military
Autotuners. Starting from scratch is going to be a BIG design project.

There's a fair amount of moderately recent literature on efficient
algorithms for adjusting a tuner. I have a recent paper from Sun and
Fidler at Univ of York that looks interesting, but I haven't read it yet.
"High Speed Automatic Antenna Tuning Units" IEE Conf on Ant and Prop,
4-7 April 1995, page 218ff

My problem as far as I can see is that the control for the AH2 is that
the innards are transferable but it only controls two motors where as
my tuner has three.
I suppose I could just use two and not utelise the fine tune inductor.
Will sleep on it for a while and look at the AH4 version or in the
worst case fine tune by hand if necessary. I suspect the fine tune is
not really necessary in most cases other than satisfy the over
zealious swr users

Putting a battery into a crystal radio is a trick I have
known abot for a while. Usually a 1.5 volt battery in series
with a 1 meg resistor is attached across the detector.
This is usually done with crystal sets made from 1n34 diodes.
The concern is that weak stations can't be received because
they can't overcome the junction voltage of the diode.
The battery provides a DC bias for the diode and increases
the sensitivity of the receiver by biasing the diode junction.
The electrons flow in the direction that a forward biased
diode allows them to flow.
```

4603. Gaussian patent

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-01 20:02:56 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <b1956a63-0e76-46b5-b648-395c0cf49fb2@d8g2000yqf.googlegroups.com>
Source record: 6753

The above has gone thru. I used a three element as my sample
illustration which in essence points to a maximum of two elements for
max efficiency. It will take an optimizer type program to explore the
intricasies of this design especially with focusing from outside the
boundary. Tho' any element can be chosen for feed but feeding all at
the same time is not really advantageous. Note that two elements
superimpose their patterns which resolve in to one. One for the Earths
circulation and you can guess what the other reflects. Note pattern
changes when mounting a vertical less than 90 degrees to the ground
surface
for all round observation. Rotation and spin can be seen as the
amalgamation of ALL the Standard Forces of the Universe as shown by
the DNA helix. The same is shown in radiation where particles resting
on a diamagnetic surface are made into a accelerated charge with spin
by applied varying current in association with displacement current
where the vector is seen as circulating thru the capacitive and the
added magnetic field contained inside the circulating displacement
current similar to that seen with a 'scope. Again we see the
observations by Gauss where the accelerating charge is the imposed
action
on a static particle inside a Gaussian boundary which is the root of
radiation and where a wave is the resulting pattern developed by the
flux movement or quanta.

> Everything has excess of electrons.

Sorry, you are wrong. A normal helium atom does not have an excess of
electrons (hint: it is inert).

Henry, the reason that you don't see many "for sale" postings on this
newsgroup is that it is against the newsgroup guidelines. For Sale
stuff should go on rec.radio.swap.

You overstate your capabilities while trying to suggest you are a
professor. Your response is a normal one after the fact. Remember you
were one of those who decided Gauss's connection to Maxwells law on
radiation was solely via his magnetic input totally ignoring his
connection via statics which is also the basis of
the Maxwell equation. When did you ever point out the truth with
respect to particles versus waves for the root of radiation? Heck, it
was only a few weeks ago that you went on about the Gaussian
contribution via magnetics and so denounce his contribution via
statics.
You can jump on the train if you want but you were never qualified to
drive it. Next somebody will point out an error and again you will

state you knew it all along! Why don't you contest some of the Nobel prize awards with your prior knowledge or win one on your own? Yes, you certainly overstate your own abilities and knowledge of the Universe.

If you can guarantee that the real part of the feed point impedance is
always higher or lower than your transmission line Z, then you can use

an L network, which only requires 2 adjustable components.

You see a lot of these sorts of schemes with physically short radiators, where the Rfeed is always less than 50 ohms.

L networks have the nice property that there's only one setting that "works" which is nice in an automated system. I think the usual scheme is to spin the C pretty fast and slowly ramp the L, and then stop both motors when the match is "good enough".

For relay based systems there are better algorithms for finding the best match that take less time.

4615. Converting terminal strip to watertight connector.

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-02 01:26:56 UTC
From: Tom Horne <hornetd@gmail.com>
Message-ID: <e3b98903-d7e4-4e8f-8a9f-809c38936c25@r29g2000yqj.googlegroups.com>
Source record: 6765

I have a Ham-M rotor that was built with a terminal strip in it's base to which the rotor control cable can be terminated. I would like to convert the connection to a watertight connector that could be made up in advance to facilitate rapid deployment and tear down for EMCOMM work as well as eliminate the corrosion that happens on the terminal strip. Has anyone done this and how did you go about it? I would also like to terminate the controller end in a connector for the same speed of deployment and tear down issues.

I thought it might make sense to use the same connector at both ends and have the same type at each end of the cable so that either end could go to either device. Any advice and cautions are welcome both on list and off.

Good to hear you again Mac. You are essentially correct
The PTO states that the patent application above
(which is 11/655,899) has been examined and is allowed for issuance as
a patent.
Prosecution on the merits is closed(underlined)
Of course, they can withdraw this notification anytime for various
reasons. Naturally this is accompanied by a request for maintenance
fees as they are a cash cow.!
Best regards
Art

I think that is what the Icom radios use as a internal tuner which I
believe is the same as the external AH 2. So with not wanting to
invent the wheel, all I need to do is uprate the motor supply of the
external tuner and transfer the wiring from the icom internal tuner.
As I said previously, I will sleep on it for a while to be sure
Regards

Mac, as a matter of fact my other patent request is on hold by the PTO
for a violation of response time.
This could hang around for a year as appeals are surging
It is said that while on hold my allotted patent time is also on
hold . Same goes with my appeal costs paid.
Seems like they are steadying the number of patents going thru for
some reason tho attorneys get relief in some way during the appeal
procedures which is quite expensive.However, the allowance is routine.
As I have said before they are a cash cow
with a vengence since the Congress took away their finances the same
way they have done with other deep pockets for their spending habits

Does it means that there is a net flow of electrons "between the antenna and
the ground".
In which direction?

So it takes a time for me to find the method of measure the Stokes drift in
your stations.
Try also to do your best.

Hi Tom:

The best way is to remove the terminal strip and replace it with a metal plate and use that anchor a pig tale of wire with a water proof connector. One of the rotor re-builders does that as one of their services. They use a plastic AN style connector. I had it done to my rotor as part of the rebuild a few years ago. If you do it your self make sure the connector can handle the current required to run the rotor. A pig tale is required as its not possable to mount the connector directly on the bottom of the rotor.

I have two of them one of which I will need to repair. They were not
on the market long. The scuttlebutt at the time was that the Bird Watt
meter folks made a visit to Heathkit to discuss the device and Heath
stopped producing them immediately. The consents (no evidence) was
that it violated patents. They work very well!

I used mine continuously in an ATV set up with 439mhz home brew
transmitters. The reflected power position is a lot lower than 25
watts so it is simple to measure considerably lower power by just
using it backwards. Someone needs to give it a good home!

Are you sure it is limited to 160 MHz? My use was primarily 439mhz.

Or may be I have it all wrong?

We used to build the electronic control unit for a now defunct
motorcycle company. They used Delphi automotive connectors that are
water proof and will handle 14 amps at 12 volt. There are many
different connectors styles and pin counts. Perhaps something in that
line would work for your application. Don't know who is distributor,
as we had to buy direct from the factory.

Another source might be an auto wrecking yard.

Well, :: Organization: http://groups.google.com ::,
he is seeing spam spam because he is posting from the in the midst of
most of the spams' origins.

Using a _real_ newsreader (`slrn`) and individual.net's newsserver,
and killfiling any google grooper's posts, I see no spam, either.

It would be easier for you to switch to a real news provider that does spam filtering at the server. You could also use a real news client with a killfile or filter mechanism. Since many users are filtering posts from google, your own posts will receive a wider audience.

Visit http://www.eternal-september.org for access to a decent free server.

On Nov 1, 10:21 pm, Art Unwin <arthurun...@gmail.com> wrote:
Before this thread gets out of line again let me make clear a couple
of points that some have got hold of which has led them astray.
First it is well known that Gauss was a part of the equations of
maxwell with his contribution on magnetics
I focussed on Gauss's contribution via statics using the boundary
rules. It can be seen that applying a time varying current to a
gaussian field is exactly the same as Maxwells first equation! Yes you
have to convert from cgs units to show this but it clearly places
particles as the root of radiation.
The second point that some planted themselves on was that all
elements were resonant and therefore all should be fed. The real point
here is that all being resonant
showed the presence of equilibrium which is a must in all equations.
It also showed that with a minimum of two elements all radiation is
accounted for where-as with the yagi which is not in equilibrium has
losses because the last element added fails to recover remaining
available radiation. This is not about getting a better antenna than a
yagi since the latter utelizes available radiation with less waste
than others. The patent is really about obtaining knowledge that fits
the bill of Maxwell's first equation and points to the static particle
accelerated
into a charge by a time varying current. It also brings into question
that put forward by the London brothers regarding cooper pairs as well
as the relationship of a proton. It also makes clear that the double
slot experiment
is correct in stating that particles and waves have similar
properties but makes very clear that the subject at hand
is very much a particle. Thus the bottom line is that Gauss provided
direction with respect to the static aproach AS WELL as the more well
known magnetic connection. It is also important to state again the
importance of maintaining equilibrium when persuing the laws of
Maxwell. I would also like to add my assertion
of just two vectors as the sole constituents of the standard model
that Einstein earlier suspected.
At the same time Maxwells law has not been fully satisfied as it has
not removed the intrinsic resistance of the radiators because of the
presence of skin effect and thus the magnetic field which has no
contribution to the accountability of all forces. However it is
important to note
that in superconductors removal of the magnetic field
achieves the desired action as would a Meander style radiator where in
the absence of skin depth the current
would rise to the surface thus eliminating resistance losses incurred

by the radiator, which now can add to the desired maximum radiation
efficiency by tackling the
radiation resistance, that is the only resistance left.
Thanks for your time
Regards
Art.

Jim, thinking a bit more about the pre conditions you gave regarding
the feed line impedance. The only way I can think that you can be sure
that the antenna never goes below that impedance is to have a ladder
line of infinite length used as feeder and the load or the load in
Meander radiator form
The ladder line being Meander in form regardles of physical
arrangement. Of course it would have to shielded to prevent static or
proximitry effects. But the question remains as to why you imposed
your conditions! Can you share what you had in mind?

An L network match either Rload>Rgen or Rload<Rgen, depending on which side the shunt element is on.

In autotuners using an L network (e.g. the LDG boxes), they have a relay that switches the shunt C to either end of the series L.

In autotuners using a Pi network (e.g. the SGC boxes), there's shunt elements on both ends, so you can match anything (subject to the component ranges).

So if you have a motorized C and a motorized L, you'd need to add a relay to switch the configuration to be able to "match anything"

By the way, a L or Pi network cannot match Rgen=Rload, but you can do it trivially setting both C's to zero and the L to zero. It's not really an L or Pi (or T) network then, which is why some automated network calculators choke on it. A real autotuner doesn't care, because it almost always starts in the "bypass" position anyway.

Hi, Folks.

I need ideas for CHEAP and uv stable, strong, light weight, waterproof ladder line spreaders of about 4 or 5 inches wide. Wood in any configuration will not do. PVC pipe will not do. Welding rod would do but it is expensive.

I was thinking of Fiberglas tape, twisted and put in place and then resin applied but that is very cumbersome.

Any ideas out there?

Thank you.

Go to Walmart and ask the bike assembler for the plastic front fork
separaters shipped with the bikes. He would throw them away otherwise.

4640. Distance to Fault

Hi all,

For my project, I want to perform Distance to fault measurement in the cable connecting the antenna. The principle is that a signal should be sent to the cable and using the forward and reflected voltage VSWR should be calculated and should be viewed in a spectrum analyzer. My question is

1. What transducer is used to detect the transmitted/reflected signals from the cable?

2. Should the transducer be connected in series or parallel?

Anyone, Please help

Why not PVC pipe?
The old W7FY 600 ohm separators seemed to
work well for me. They would seem to be light, stable
strong, and waterproof over the 9 years I have had
my dipole up.

One half inch black plastic irrigation tubing is inexpensive and
designed to withstand the elements. Cut it to length, drill opposing
holes at each end (a little smaller than the wire insulation) and cut
a key-hole slot from each hole. Clip the holes around the wire and
enjoy.

PVC pipe works well, I wouldn't reject it. Better yet look at plastic gray conduit. It's made to stand up to the sun and is cheap and light. I used it to make some 600 Ohm line for my antenna.

All forms of communication seem to have some sort of noise level.
Any attempts to filter out the noise also loses part of the signal.

So far, I find the noise level tolerable.

That is a great post!

I am slowly working towards a motor driven remote T-Match roller
tuner. I intend to use the same algorithm that I use to operate a
manual tuner.
That is to start with the capacitors at center, the inductor at
minimum. Run the inductor down until the minimum SWR and center it
there. Then do the same with the transmitter side capacitor. Finally,
do the same with the antenna side capacitor. The controlling SWR
signal is from the transmitter point.

I am concerned about making the transmitter happy as quick as
possible. I expect that this is not be the optimum match but it will
serve the purpose of making the transmitter happy.

I start with the inductor because the losses are greater there so less
inductance is likely to have lower losses. I had overlooked that I do
try shunting the tuner first.

After having explained that I realize there is probably a better way.
I will try starting with Max transmitter side C, Min Inductor and

Minimum antenna side C.

I think the ideal procedure would be to calculate the needed match,
build it to minimum loss (in the tuner) and switch it in. I will have
to think about that...

No transducer. Use an oscilloscope to measure the time between the
emitted pulse and the reflection of the same.

Forward and reverse power are normally resolved using a "directional coupler." Such a coupler can also be thought of as a bridge circuit. Directional couplers can be built in various ways. For example, the free-ware RFSim99 program, under tools-->component-->coupler shows five different ways to build a directional coupler. That program doesn't show the Wheatstone bridge form of directional coupler, but those are also common, especially where a wide range of frequencies is to be covered. Wheatstone bridges are generally used with equal (e.g. 50 ohm) arms in test and measurement equipment that runs low RF power (because such a bridge must dissipate most of the RF power fed to it), and with very unequal arms when high power is to be handled (resulting in a low coupling factor; -40dB is common). Please note that directional couplers must be designed for the impedance line they are used with (and ideally, the calibration should be verified).

In your project to locate faults, you may wish to consider not only the ratio of forward and reverse power (e.g., SWR), but also the phase relationship between the two. The rate of change of phase as frequency is changed should tell you how far away a single fault is; multiple faults are more complicated.

Cheers,
Tom

Maybe. But I proffer it to point out that Maxwells equation for radiation is nothing but a formula if one concentrates on the electro magnetics approach. It is the electro static approach of Gauss of adding a time varying field to a Gaussian field to obtain maxwells first equation, where the equation is given informative meaning and direction which has deluded all for the past century. With respect to the pursuit of equilibrium for all equations the idea that all elements within a Gaussian boundary should be fed because they are all resonant is a fallacy, as is having more than two elements. Newtons laws demand only two opposing vectors to oppose the vectors of gravity and spin which are the pillars of the "standard model" which with respect to radiation show them selves as the direct variant current vector and that of spin. I make a point of that because it points the way for maximum efficiency by removal of resistance created by skin depth restrictions to current flow to member surface. All the above can be ascribed
to taking the statics approach in the exact formulation of Maxwell equations, instead of the route taken by Maxwell by his addition such that all units of his equation canceled out as required for equilibrium. So yes, there will always be bickering when change is suggested but the usual case is that a presented theory is technically challenged by one peers rather than by taunts and jeers.

Didn't think of that. I wish they made 1/4 inch. However, I will
surely look at it.

Thanks

I was concerned about weight, John. How many do you have on your feed line?

If you want to automate this, you really need to know more than just the SWR (or magnitude of Gamma, the complex reflection coefficient), or a related signal (such as 'relected power').

Have a look at some practical implementations, and see how they work.

You have a three variable problem to solve, and one input value (using your proposed method).

>
> I am concerned about making the transmitter happy as quick as

Ah, 'happy' transmitters, as in the ATU's purpose in life is to make the transmitter happy.

> possible. I expect that this is not be the optimum match but it will
> serve the purpose of making the transmitter happy.

One of the design decisions you should make is how close to perfection is the target 'match', and what do you do if it changes during operation.

Can you determine an optimum match (meaning VSWR=1, efficiency=max) using SWR?

>
> I start with the inductor because the losses are greater there so less

In the real world, it gets a little more complicated that the classic Rules of Thumb (RoT). Inductor Q is not constant with varying L, capacitor Q (or D) is significant if ceramic caps are used (as in many

autotuners).

>
> After having explained that I realize there is probably a better way.

If it were me, I would create a software simulation of the algorithm, and include real physical times in the simulation. See if your algorithm converges on a stable and correct solution, and then, how quickly it does it.

look up time domain reflectometers... they are much simpler than what
you are thinking of. using a simple step input wave you measure the
time to the reflection. if you get fancy you can measure the polarity
and size of the reflection to determine if it is a short or open or
impedance change... if you really get fancy you can hook a scope up
and look at more details. the only transducer needed is a voltage
probe OR a current shunt, either one will work depending on the
installation needs.

One concern about black plastic tubing...

some kinds use carbon black as a filler, which makes them resistive.
Probably not an issue for relatively low voltages in an RF feedline, but
not good for the Van deGraaff generator, etc.

Or, use the technique used in vector network analyzers..

Sweep the frequency, do the fourier transform to find time domain.

If you're using just power detection, it's more like getting the
autocorrelation or power spectrum of the reflected signal vs frequency.

Owen
Most radios have a tuner inbuilt or as an add on.
These types are ripe to uprate the components for high power for
placing at the antenna whilst keeping all the controls at the
operating position. This way you keep the lower power timing and other
tuner controls in position as well as the memories and of course band
changes so you don't have to reinvent the wheel or use skills that you
don.t have

If the school project requires him to use a Spectrum Analyzer, then the time domain may not be an option.

if the school project is requiring a spectrum analyzer to measure
distance to a fault location then its a pretty dumb project. there
are much better and more straight forward ways to do that.

One other thing that I have seen mentioned on this newsgroup, is
plastic clothes hangers chopped up. They are about 3/8" in diameter
and are cheap. Not sure about UV resistant.

I've used those for small insulators. They do break down and
get brittle after a while. But it takes a while. Being as they
wouldn't be holding as much strain compared to using them
for end insulators, they might last a fairly long time before
one broke at one of the holes.
But the UV will do a number on them in the long term.
Little strips of clear Lexan window material might last for a
fairly decent amount of time. It's pretty strong, so will take
a while to get weak enough to break with the fairly low
tensions involved.

An observation about wetting agents. As I have stated before
diamagnetic materials are tightly bound in a skin of resting
particles. Water is diamagnetic and all are aware that insects can
walk on this skin and at the same time these particles are tightly
bound to each other that they can form droplets of water into a tight
sphere for equilibrium. One can also have a shallow vessel of water
where, when a magnet is placed on the underside, the particles will be
attracted to the skin creating deflection. Anyway
the point is that a wetting agent removes the diamagnetic features of
water and other radiative materials where the cohesivness of the
particles is destroyed. Bearing in mind that these static particles at
rest are the root of radiation it certainly does not make sense in
destroying their adhesion to a radiating surface. I imagine that any
"windows" added between the lines would affect the displacement
current as well as the enclosed capacitive field within when the
environment changes when compared to pvc spacers. I do believe that
wetting agents are applied to space vessels to ensure the surfaces are
cleared of these same static particles prior to take off.

Yup, that's the default instrument, but a fast-rise-time pulse
generator and a wideband scope will do it, too. I created a TDR
accidentally when I thought I was just measuring rise times on the
input and output of an amplifier. (I had inserted a T-connector,
creating an impedance mismatch, which showed up as a reflection. When
I saw the glitch on the trace, I puzzled over it for about half a
minute before it dawned on me what I was seeing.)

However, if this guy feeds his spectrum analyzer with a tracking generator and tee's off to the unknown cable, the reflected energy from the cable fault will generate a comb of nulls. The frequency of the first (lowest frequency) null will indicate either the quarter-wave point or the half-wave point (depending on whether the fault is a short or an open. You'd need to know the velocity factor, too. I don't see how VSWR would come into play.

Yeah, I'd really rather have a TDR, hi-hi.

By the way, this arrangement also works to approximate the resonant frequency of an antenna. The comb of nulls will flatten out -- be less pronounced -- at the resonant frequency, due to the incident energy being radiated, rather than reflected.

At first you must have a radio which do not work without ground. No chassis
no AC supply.
If you are able to prepare such the rest will be easy.

For years I used the cheapest 300 ohm twin-lead I could find, at times splicing pieces
together. I have fed T2FDs, Inverted Vee's, Verticals, once I actually loaded
a piece of wet noodle, and almost anything you could
imagine. In wind, rain, and snow I had years of good DX and other fun but never noticed
any differences which might have occured in theory -- they never revealed themselves in
practical use.

It looks like a "not-to-complicated" problem to me. I hit a wall somewhere along the way, I will have to give it a try to find out.

I am not seeking a perfect solution, just a homebrew project to solve a problem. I never thought I would own an HF amplifier but now I do. I am accustomed to the convenience of an SGC-237 tuner in the shed next to the vertical antenna. Too much power for the tuner so I have slowly acquired the parts to construct the High power tuner project.

Not a Bread board but more like a cabinet door prototype. After all, it will be on a shelf in the shed. I am thinking a PIC micro controller (I have tools & Experience) and electric screwdriver actuators.

Ugly Construction is beautiful IF IT WORKS!

BTW, it is one of many low priority projects I have...

It's not quite that simple. For example, a load of 5+j30 requires the
same L-match configuration to match to 50 Ohms as does 500+j30: shunt
C at the Load end in both cases.

Fiberglas electric cattle fence poles...various sizes, Sears and
Tractor Supply, among others, have them. Cut into appropriate size and
drill holes on eaach end. Fairly cheap.

If you live in a rural area, check the hardware or farm supply stores
for electric fence insulators. The ones in my hardware store are 5 or
6 inches long and cost a few dollars per hundred.

Or just use a grid dip meter.

1) Determine if the fault is a short or an open circuit with any tester.

2) Connect a small loop at the input of the cable.

3) Couple the dip meter and read the minimum frequency with a dip.

4) If a short circuit ===>>
Distance(meters) = 75 * cable velocity factor / frequency (MHz)

5) If an open circuit ===>>
Distance(meters)= 150 * cable velocity factor / frequency (MHz)

>got it... plastic case, battery powered, only does 5w that that is
easy to measure. now how much dc current should i measure in the
ground lead when i transmit with 5w?

You know: "more than electron per cycle and less than infinity".

For one you should use an electroscope (in place of ground).
Charge it and check what your radio needs to work (+ or -).

For more, the steem generator should be beest. "At Cramlington Colliery,
Sedgehill, Newcastle on Tyne (Northumberland, England) high pressure steam
broke through the cement around the safety valve of a locomotive boiler. The
Engine-Man held a shovel in the steam and with a penknife in his other hand,
held about 3/8 inch from the boiler, produced electric sparks.".

In such arrangment the shovel has an exces of electrons and the boiler a
deficit.

Close to infinity the DC meter will be enough.

But the experts know that Stokes drift is everywhere.
Stokes drift and longitudinal electric waves in the wires (Oliver Lodge)
were discowered before electrons.It is obvious that the both apply to the
electron gas.

Electrons also travel through a capacitor. AC pulses are never simmetric.

4686. how to hang a 120' / 40m drop in foamed RG6 ?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-05 09:50:54 UTC
From: spamhog <n1jpr@hotmail.com>
Message-ID: <2778834e-4e89-4496-95b2-8e65e3b0cde1@f20g2000vbc.googlegroups.com>

PROBLEM

I have to hang a straight ~120 foot = 40 meter drop of RG-6 type foamed dielectric coax. No way to secure it mid-way as it's an abandoned and unaccessible chimney flue line.

Right now all the weight is on a rounded rest on top, diameter ~ 4"/10 cm, made by sticking 3 rubber pipes of different size one inside the other and taping the coax to itself, leaning on a section of plastic pipe

The weight is quite ~ 5 kg if I remember correctly. I think there is no way that leaning over a 10 cm. dia. rest won't crush the foam dielectric over the years. I may be wrong, but finding out is not simple at all.

This thing now only carries HF and a bit of crushing is not important (+ I can't easily test it!), but I want to make sure I can do 2 GHz in the future, and I don't know the proper or standard way of hanging a LONG vertical coax drop.

Now I have a chance to re-hang the coax, and I want to run it along a load-bearing PVC-covered steel cable, perhaps 4 mm dia.. The coax itself is the usual 6 mm -something. I am considering a couple of options:

1) Three more loops, to have a support loop every 10m or so.
The cable drops from the top loop, then after 10m gently bends back upward, then forward again over an arched support, taped to itself, and continues the drop.

2) Many many nylon straps all along the drop.
I lay coax and steel cables horizontally. Keep the steel cable taught, leave the coax loose, and gently tie a tiny nylon strap every meter or so, barely to the point it holds 1 meter's weight, taking care not to strangle the coax.

Suggestions? Comments?

There's no such thing as a perfect capacitor. Electron flow through a
capacitor is what causes it to fail eventually.

Conversely, a load of 10+j22 needs the shunt C across the load,
whereas 10+j18 needs shunt C across the generator.

This is wrong and shows how little you understand.

If you continue to rely upon web pages that are written from grade school
kids you will never understand.

Leave your outdated and overly simplified references behind and try learning
from a modern textbook.

Everywhere is wrote that a real insulators are a very,very week conductors.
At HF it increases. Net flow of electrons is in each real arrangment.

A suggestion.
When the cable TV guys ran the distribution line past our house a few
years ago they spiral wrapped stainless steel wire around the coax and
a messenger cable. The coax was the regular pvc type, not the solid

aluminum outer cover. It seems to have held up at least 10years.

They used a traveling spool carrier to spin the wire around the pair, but could be done by hand by a couple of people.

As an alternative, you could buy a bunch of plastic tape and wrap the coax+messenger tightly with at least two layers of tape. That would give continuous support to the coax. A double wrap would probably survive the elements better than a single wrap. Or you could get several bottles of "liquid tape" and coat a single wrap of tape with that.

I think what you are doing has potential 'problems', but you know
that. More support for that cable is certainly a good idea. The
'how' of it is one of those practical thingys, just depends on what's -
practical- for you.
I think you'll also find that RG-6 probably works okay on HF and VHF.
Get any higher in frequency and depending on the length of the run,
you can forget about using any of the 'common', non-hard line feed
lines. Get ready for that.
Either of the methods of supporting that feed line sounds like they'd
work. Pick whatever is easiest for you. And there ain't no 'perfect'
way of doing anything...

ok, i put my electroscope in place of ground, no movement in the gold leaf when i transmit. i also borrowed a very sensitive electrostatic voltmeter and do not see any voltage buildup on the radio when i transmit.

and my rf waves are as perfectly symmetric as i can measure on a scope, even taking one and delaying it 180 degrees and subtracting from the source gives me a flat line that i can not measure any distortion on.

so, what is your predicted shape of these distorted waves?? i see a nice sine wave function, you must have some other solution for harmonic motion and the wave equations, please provide your solution that includes the asymmetry terms we should be looking for.

there are cables made that include a steel messenger cable. if you
need to use what you have then get some aircraft cable and tape your
coax to the steel cable.

One other thing that I have seen mentioned on this newsgroup, is
plastic clothes hangers chopped up. They are about 3/8" in diameter
and are cheap. Not sure about UV resistant.

Gary N4AST

These are generally polystyrene and their UV resistance is not too bad.
They are cheap!

4697. Glen Martin Engineering = Rooftop Towers

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-06 03:31:58 UTC
From: Barry <none@nospam.org>
Message-ID: <L_3Bo.6711$xb.4221@newsfe10.iad>
Source record: 6847
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

The addition of a new metal roof to my home has prompted my interest in a small rooftop tower. I am considering the Glen Martin Engineering 4.5- and 8-foot aluminum towers. However, in doing some research on the company, I have read many reviews (particularly on eHam.net) where people brought up shoddy workmanship such as misdrilled holes, double-punched slots, burrs, incorrect documentation, missing parts, etc. Many complaints were about shipping too. However there also were several people well-satisfied with their products.

Because of this, I decided to check with the Better Business Bureau of Boonville, MO, where the company is located. They have a B+ rating, and the judging criteria of the BBB tends to give the company an overly positive rating in my opinion. Interestingly, SalaryList.com gives the fall 2006 salaries of design engineers at Glen Martin to be $41K and that of a project manager to be $32K. The average salary for the county at that time was $26.4K. I consider these to be rather low. I have not seen any ads by the company in QST recently either, and the League has stringent standards for any company advertising in a League publication.

None of this gives me a "warm fuzzy feeling" about the company and its products, but I am willing to keep an open mind. I would therefore appreciate any readers of these newsgroups posting their experiences with the company and its products.

My application, by the way, is to support a 43-foot vertical and small Yagi's for 6- and 2-meter SSB.

Your radio do not transmit without ground. The leaf are not the inexhaustible reservoir of electrons.
Charged electroscobe is a tiny rasevoir.

>and my rf waves are as perfectly symmetric as i can measure on a scope, even taking one and delaying it 180 degrees and subtracting from the source gives me a flat line that i can not measure any distortion on.

Working transmitter is like the Ruhmkorff coil or Tesla coil:
"In April 1887, Tesla began investigating what would later be called X-rays using his own single terminal vacuum tubes (similar to his patent #514,170). This device differed from other early X-ray tubes in that it had no target electrode. The modern term for the phenomenon produced by this device is bremsstrahlung (or braking radiation). We now know that this device operated by emitting electrons from the single electrode through a combination of field electron emission and thermionic emission. Once liberated, electrons are strongly repelled by the high electric field near the electrode during negative voltage peaks from the oscillating HV output of the Tesla Coil, generating X rays as they collide with the glass envelope."

The both are like the electron gun. They do not work without the electrons reservoir (ground).

>so, what is your predicted shape of these distorted waves?? i see a nice sine wave function, you must have some other solution for harmonic motion and the wave equations, please provide your solution that includes the asymmetry terms we should be looking for.

For equations see "Stokes drift"

Each pulse from a wave source, whan reach the end of the antenna, create the high voltage pike. Next the voltage drops and create the opposite pike. In reality they are not symmetric. In Ruhmkorf's the first is huge and the second almost zero.

But you know that the antenna must be tunned. Probably the field emission starts after tunning.
It would be interesting to measure the voltage pikes on the tip of CB whip before and after tunning.

If the voltage pikes are asymmetric than the field emissin/absorption also and we have Stokes drift.
Look at: http://remeeus.eu/english/hamradio/artificial_ground.htm

It is simply chassis with large metalic surfaces.

How to mesure Stokes drift - it is a question. I am sure that the experts did it from the radio beginning.
I am not an expert.

Thank you all!

@K1TTT
Yes, that's the technically idea solution, but I am trying to use common materials that cost perhaps 5x less around here.

@'Doc
You have a point. I wrote RG-6-"type". There's a ton of various cables types that are sold commercially as "similar" to RG-6. I referred to the sat-tv cable that everybody uses around here, and you find it in every electrical supplies shop. This cable is designed for use at about 2GHz, which is the IF at which signals are sent down from the LNB to the receiver.
- solid copper center conductor
- foamed PE dielectric
- 100% AL first shield, perhaps .1mm foil
- probably 60% AL second shield, stranded
- insulation 3kV DC test, in practice not a problem (if you don't crush/melt the foam :-)
- emphatically NOT rated for power, tested and perfect up to 50W QRP and RX, theoretically could take 1kW if well matched and not overheat (see specs, do the math) but I never tried and ever will, I'd guess will take 100W OK. I should do a high-current DC test perhaps.
- pain in the rearend to mate the AL to anything, must be pressure-only, must be silicon grease coated on penalty or corrosion, but after all this is how perhaps 300 million sat-TV systems work at 2GHz.
- loss 2dB/100m (m not ft) @ 10MHz, not bad
- ...75 ohm, but I either make my own impedances, or not care, or use tuners, and 75 is OK for many applications.

@KD7HB
Plastic tape is probably the simplest and best, perhaps without even wrapping the whole length - at a 30deg. angle spiral wrap I would need 240ft of tape! :-P. Also, tape is much gentler than sttap in terms of pressure per unit of surface. Dish installers never use nylon straps outdoors, just several turns of black, weather resistant PVC tape, and it lasts at least 5-10 years. In my case, the drop is all inside a flue line, well protected. Maybe I should use a large rope just for wider surface. I'll do an overload test and see.

But another post around her tells me that perhaps there's a was to test the line at 2GHz...

Thanks again to all.

4700. Re: Distance to Fault

Message-ID: <ea3b80d3-a880-47b0-bb9b-33f7a62eb261@k13g2000vbq.googlegroups.com>
Source record: 6850

I have a similar practical real problem.

A vertical 120 ft working 75 ohm coax line hung from the top.

The soft foamed dielectric MAY be crushed under the cable's own weight
10 ft from the top end.

If it is I must change the hanging system.

ASSUMPTIONS
- the dielectric is crushed to 1/2 the original thickness over 2
inches length 10 ft from the far end
- I can put a good quality non-reflecting 75 ohm load at the far end.

QUESTION
Can I expect such a defect to generate a detectable reflection at
2GHz?

4701. feeding random inverted V for RX

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-06 10:39:36 UTC
From: spamhog <n1jpr@hotmail.com>
Message-ID: <8319f44c-88c1-4ed1-aebd-a0fda42a3f44@j5g2000vbg.googlegroups.com>
Source record: 6701

I want to make a random-length inverted-V for general listening and perhaps, maybe, occasional HF work, no pretense to have perfect match or minimum losses. I see much discussion about feeding a random dipole with 450 or 600 ohm ladder line.

I can lay a low loss 75 ohm line but absolutely not a ladder line, so I'd have to put a balun at the apex

I'd cut a dipole of about 15 + 15 m (50+50 ft), 120 deg. inverted V, apex at 15 m.

I could do 1:4 -> 300 ohm or 1:9 -> 625 ohm.

What would be the least-bad?

Thanks in advance!

just wind a coil choke, that will be cheaper and no worse than either
of those options.

rg6 or 11 with steel messenger may be common depending on the local cable tv practices. it is often used for running drops from the pole to the house by catv installers.

rope would work in place of the cable, but pick a non-stretchy one. polypropylene would be my first choice since it will be out of the weather. and yes, only a couple turns of tape every 3 or 4 feet should be plenty. and since it is enclosed you may not even need to go all the way down, just enough to get to where you aren't afraid of the weight of what is left stretching it any more.

i have measured the voltage at the tip of an antenna, it is a nice
sine wave, no spikes. we don't use spark gap any more if you haven't
noticed, modern radios use nice symmetric sine wave circuits. if we
didn't have nice sine waves there would be harmonics that would
interfere with other bands. your distorted waves would be horrible in
today's world. look up specifications for distortion in radio
transmitters and then go study fourier transforms to see the effects
of distortion on the spectrum of the signal. i am bored, you have no
new theories like art does, you just keep picking random unrelated
facts, so this just isn't fun any more.

I have a Heath HM-2102 VHF SWR meter 50-160 MHz
0-25 and 0-250 watts. Very good condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

I have not even seen any of their products but they have been around
for a while.

When you undertake a project like this it is important that you
consider your expectations. If you are unwilling to solve a few
problems as you go it would be best if you contracted with some one
else to get the job done.

Installing an off site fabrication seldom happens without a few
problems. If the manufacturer is willing to work with you it helps. If
not, you must be prepared to solve the problems on your own.

They have some products that are not available anywhere else. You may
be unable to realize your objectives without their products!

BTW, public figures are seldom reliable. There are a lot of business's
that are not run with simply a profit motive.

Yes. The cable impedance will be lowered in the vicinity of the crush.

A good time-domain reflectometer can see the impedance mismatch of
connectors - even you are using types C, N, TNC or BNC. UHF type
connectors, such as the PL-259, are readily seen. Your section of
crushed dielectric should "stick out like a sore thumb" on a TDR trace.
Termination at the far end is not necessary but it will make the
understanding of the TDR waveform easier.

Impedance mismatches, even though they are short in length, become more
important the higher in frequency as you go.

This site is primarily chimney mounts and a few galvanized steel tripods.
The house does not have a chimney (after all, I live in SC), and a tower
with four legs is preferable to a tripod when roof-mounting an antenna at
the apex.

Yes, and their manufacturing problems have had ample time to be fixed by
now. The reported complaints seem to be evenly distributed over time
from the early days of the company to September of this year.

> When you undertake a project like this it is important that you
> consider your expectations. If you are unwilling to solve a few

These rooftop towers are trivial in design and construction. Rohn and
other tower companies seem to have no major complaints. Why should I
have to solve their manufacturing defects?

> Installing an off site fabrication seldom happens without a few
> problems. If the manufacturer is willing to work with you it helps. If
> not, you must be prepared to solve the problems on your own.

In Glen Martin's favor, most reports say the company has been good in
supplying replacement parts. Better quality control would save their
company money over having to ship replacements.

> They have some products that are not available anywhere else. You may
> be unable to realize your objectives without their products!

Their rooftop towers are so simple to build, a local fabricator could
easily build one. Getting the 308 stainless hardware locally in small
quantities is a problem, but welded construction would eliminate the need
for most of this.

> BTW, public figures are seldom reliable. There are a lot of business's

Glen Martin Engineering is a woman-owned company, and while I have known
many fine woman engineers and managers, this is typically done in small
businesses for the tax advantage (minority ownership). I seriously doubt
that they are not run for a profit!

4714. Random wire vs ANLP1

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-07 01:46:03 UTC
From: Bajamatic <Bajamatic.71bead9@radiobanter.com>
Message-ID: <Bajamatic.71bead9@radiobanter.com>
Source record: 6714

Today I started experimenting with listening antennas. My goal is to find something I can pack in my truck and set up deep in the heart of baja for weather nets. My first purchase was an ANLP1 active antenna and that works great because right now I'm using a G5 portable radio which like the ANLP1 has a mini Jack connector. However I'm making a big upgrade in the radio departmnet (probably a aor7030) so I wanted to start testing against the ANLP1 to get some antenna intel and a random wire was the obvious first step. At first glance the random wire seems to work a little better than the ANLP1. At times the wire seems to pull in more signal and at times it's almost exactly the same. The wire is 100 feet long and hanging about 30 feet up. The ANLP1 is about 20 feet up. So I have some questions for all you folks who know lots about this stuff. Thanks for any info you can share.

Is this a suprising result? I kinda thought the active antenna would outperform the wire.

Will a tuned mutliband really be that much better?

If you were going to make an antenna that's relatively easy to store and set up with the goal of getting some
fun radio stations and a handfull of sideband stations what would you opt for? I would define easy as raising a 30ft guyed mast as relatively easy. A 140 foot multiband wire antenna off that would be pushing the limits if not too much space.

And finally, will the reception of the ANLP1 increase very much if it's 30 feet up?

Thanks for your time helping out a rookie. I'm slowly being sucked in!

You don't tell enough specifics to judge your experience. Frequency,
time of day, antenna orientation all play significant factors.

However, as you are going into a desert location (or at least a very
much less populated area), you are going to have less noise to contend
with, and less interfering signals (out of band signals like AM
stations can seriously de-sensitize your receiver). All this bodes
well for a simple wire antenna (and not necessarily goliath 100
footers). Any additional equipment would be an antenna tuner (a very
cheap version of what Ham radio operators use for transmitters - so
you won't need those power/SWR meters) and some form of ground - if
only another wire trailing along the ground.

Sounds normal to me. The loop on the active antenna is
very small. Not a heck of a lot for the preamp to work with.

Not for most signals. Only if they were line of sight.

>
> Thanks for your time helping out a rookie. I'm slowly being sucked in!
>
> --
> Bajamatic

If you are receiving, you really don't even need a feedline for
random wire antennas. So I'd just take a roll of wire and throw it
up to match the site. Heck, take both of them if you have the
room. But if I had to choose one, I'd take the wire.
Even 50 feet should be plenty. And it doesn't have to be high
off the ground either.

I camp quite a bit, and have often transmitted with dipoles as low as five or so feet off the ground when I had no trees or tall supports.

I've got a place out in the sticks, and I always have a radio there, but I have dipoles in the trees that I leave there. I run 80 and 40 dipoles on a single coax and the apex is up in an oak tree about 25 feet or so. I've got about 100 feet of RG-58, so it will pretty reach
anywhere around the camp or driveway area. I usually stick the radio on a stone bench I have there and power it off the car.
When I leave, I roll up the coax and hang it on a tree branch stump.
This was about three weekends ago.. Weather net on 75m I stumbled across.. Scuse the camera focus hunting.. :/
http://home.comcast.net/~disk100/radio.wmv

BTW.. the antenna is resonant 80/40, but I have no trouble receiving any other HF frequency. When I was there three weeks ago, all bands were open up to 10 meters and I had no trouble hearing any of them. Receiving is just not very critical.
It even does OK on VHF.. I listen to the local sheriff dept, etc at night sometimes. I have no trouble hearing them on that HF antenna.
I've got to where I use the radio more out there in the sticks than I do here at home.. :/

Well, it _might_ get the device up and away from local _noise_ sources.

Source record: 6720

Which antenna is better: 5/8 wavelength vertical or a J pole?

Frequency of operation is 145 MHz = 2 metres.

The 5/8 wavelength vertical has a loading coil. There are losses in the coil.

The J pole has a quarterwave matching stub. The matching stub provides an out of phase current which means that there is a cancelling field close to the radiating element. Also the J pole is end fed, which means the transmitter is not connected directly to a maximum current point.

Does the J pole have a disadvantage because of the cancelling field from the matching stub and the fact that it is end fed?

Also consider gain and angle of radiation.

I have one Glen Martin product, a ground rod driver that is
beautifully made and very effective.

Otherwise on your roof mounts, it would seem the trickiest part would
be drilling blindly through your roof to attach the rather substantial
Glen Martin towers to attic beams. Plus whatever leaks the process
might create.

Better for what? For example, a 5/8 whip would usually be better than a J Pole for mobile applications on a car roof, but that doesn't make it better for all applications.

>
> Frequency of operation is 145 MHz = 2 metres.
>
> The 5/8 wavelength vertical has a loading coil. There are losses in
> the coil.

It is certainly popular to talk down an antenna with loading coils or traps because they are "lossy".

Everthing in a real world antenna has loss, the issue is the magnitude of the loss, and the impact of that on system performance for the intended application.

You might find it hard to believe that some antenna systems incorporate loss elements in order to reduce feed line loss by more than that in the introduced elements.

Whilst you have chosen to raise the loss in the coil, you haven't raised the issue that a J Pole has currents flowing in lossy conductors, components of which that do not directly contribute to radiation.

>
> The J pole has a quarterwave matching stub. The matching stub provides
> an out of phase current which means that there is a cancelling field
> close to the radiating element. Also the J pole is end fed, which

This is not a very good way of analysing the J Pole. The U section can be thought of as carrying currents that have differential and common mode components. The common mode components contribute directly to radiation field. You should also consider common mode current on the supporting structure and feedline.

The 5/8 wave vertical also has potential for significant common mode current on the supporting structure and feedline, you need to look at the effectiveness of the decoupling method employed (usually a radial set).

> means the transmitter is not connected directly to a maximum current
> point.

What does that matter? BTW, neither is the base fed 5/8.

There is a maxim in ham radio that antennas should always be fed at a current maximum. You could subscribe to that, but you would limit yourself by excluding a range of good solutions, and with no guarantee that a current fed antenna is optimum.

>
> Does the J pole have a disadvantage because of the cancelling field

There is not perfect cancellation at all points on the U section.

> from the matching stub and the fact that it is end fed?

"End fed", as opposed to a centre fed dipole perhaps. But isn't the 5/8 "end fed"?

>
> Also consider gain and angle of radiation.

The three dimensional gain distribution is important, but dependent on the common mode issue mentioned above (amongst other things).

It is fair to say that J Poles are very popular, and that they are overly represented in problems discussed in online fora.

On the other hand, the 5/8 which was once very popular for mobile work in this area, is long lost, replaced by two, three and four band antennas where VSWR is more important than any other performance parameters. I use a 5/8 vertical on my car, and regularly work repeaters mobile at distances well over 100km. The antenna is more than thirty years old, and has never required repair despite hitting low trees, carpark roofs etc lots of times. The modern multiband antennas are not that robust. I wouldn't even think of a J Pole in this application.

So, "best" can be a quite complex requirement.

Owen

If he's out in the sticks, there should be no local noise sources.
That's one reason why he really doesn't need to even use a
feed line per say. Local noise should not be an issue.
And if there were any power line noise from the general area,
elevating the antenna will just increase it if it's line of sight.
For sky wave signals, elevating that small loop is not
worth the trouble out in the Baja which I assume is a semi-
desert type terrain. It should do almost as well low as it
does elevated.
As long as the signals are not local line of sight, even the wire
antenna doesn't need to be too high. Five feet off the ground
will work just fine for most HF reception that is sky wave.
With a decent length wire, you will still have more signal
than is required for any decent radio. And almost anything
made these days is fairly sensitive. Even the cheap portables.

>
> Also consider gain and angle of radiation.

They are both "problem" antennas.. The usual 5/8 GP
is a problem antenna because years ago some designer
decided to use 1/4 wave radials instead of 5/8 or even
3/4 wave.
And most ignore common mode issues.

The J Pole often suffers because most tend to ignore
common mode issues, which leads back to lame
incomplete antenna design. :/

Both can be greatly helped by adding decoupling
sections at and below the feed point.
The 5/8 antenna should be run as a collinear
with dual 5/8 elements.
And with a lower decoupling section.
The dual 5/8 collinear is more effective than any
half wave vertical, even if the half wave is decoupled
from the feed line.

BTW, I have no real issues feeding from a high voltage
point. And the loss in a 5/8 loading coil is probably
not enough to even measure for most people.
Both are non issues.
The real issue is lack of decoupling, and using a
perverted 5/8 over 1/4 wave element scheme in
the case of the usual 5/8 ground plane.

The perverted antenna design actually ruins the pattern of what would be a decent antenna if it were designed correctly with dual 5/8 elements. Even running 3/4 wave sloping radials is much better than using the usual 1/4 wave radials.

Of course, mobile 5/8 whips are only the upper half of the antenna. They don't supply the lower half in that case. For those, the vehicle is the lower part of the antenna and performance can vary from good to horrible depending on where it's mounted.

I guess I should chime in

I have the Glenn Martin 9ft Roof tower and Im extremely pleased with it. Its very solid and I can stand on it and shake it and it doesn't move (and I'm
a very heavy guy).

The assembly went well with only a few minor tweaks for holes. Not a BIG ISSUE. I swear half the people that complain would rather have tower
fairies show up and assemble them. If you dont want to do a little work dont buy this tower.

The shipping was very fast to my northwest home and Yes they did make an error. I bought the 9ft and they sent an 18ft. They told me I could
keep the 18 ft as it was their mistake. But that would not have worked at my QTH. So they sent UPS to pick up the very next day and I received
the 9ft very rapidly as they Expedited it.

I have an A4S up there and its all solid.

as far as install

I set the tower on 2X4s on top of the roof under the tower feet, predrilled for long lag bolts. I roof tared under the 2X6's and down in the holes before
I Installed the tower. Under the Rafter I have 2 2X10s that are 10 feet long. The bolts come down through the 2X4s, the roof then down through the
2X10s. Its all pulled snuggly up and that distributes the load over the rafters.

Ive not seen any leaks yet in a year + its been up.

Count me as satisfied.

Scotty W7PSK.

Maybe you have the coax and steel cable for free, but ...

why not use the coax used for cable tv service drops which has the coax
and steel cable integrated into one assembly? It's got the jacket
integrated with the supporting cable, so the loads are very evenly
distributed, etc.

Thanks for all this info. As i'm still just listening, I think I'm starting to understand that all the tuning and matching is somewhat irrelevant to my needs. There is literally nothing for miles where I'll be deploying this and all I really care about is catching the morning weather round up around 7250 kHz and then whatever else I can pick up while sitting fireside. So far the random wire seems like the cheapest and easiest way to go, and maybe even the best all around performer. I figure I'll get a spool of wire and run it at least 4 feet off the ground - is that really all I need to do?! Since thats so easy, I'll probably play with a SUPER long one (500 feet+), and then find the best balance between performance length and convenience. Two more questions before I put it to test:

will if effect the performance if the antenna comes into contact with the ground?

Will I get the same results if I make a 20 foot x 20 foot square and run a huge length of wire along the perimeter at different heights so as not to short but essentially 500 feet of wire run around a shape instead of in a relatively straight line?

Thanks for all your insight.

Hello,

Two questions, please:

a. Is there some way to tell if a USB cable is USB 2, or if it is an
older version ? Some symbol on it, perhaps ? What about for USB 3 ?

Is USB downward compatible for USB usages ?

b. Any recommendations for an indoor antenna for HF (<30 MHz) that
would be omni-directional, and really small in size ?

Would like to have something reasonably sensitive that might fit on a
desktop, or on top of the radio itself.

Would it have to be an active-antenna to meet this criterian ?

Thanks,
Bob

small hf receivers come with a simple extend able whip and an internal
ferrite stick for the real low bands... this is adequate if you are
just swling and stuff like that. a separate active antenna would give
you more flexibility in case the spot where the radio is has too much
noise from being near a computer or tv or something like that.
dropping a wire out a window or even running it around the frame of a
window is also a way to hide a bigger antenna. for the most part when
you are inside like that you are going to be more limited by local
noise than signal strength on just about any antenna.

Take care to anticipate that this long an antenna may well have to
pointed at (lengthwise) the station you want to receive instead of
pointed broadside to it.

>Two more questions
>before I put it to test:

Yes - more loss. However, the troops in Desert Storm did it in the
sand dunes; but they were only talking to local operations - not DXing
Andorra.

Re USB: So far, I've had few issues intermixing USB 1.1 and USB 2.0 devices. The one exception: my old Win-98 laptop doesn't like large thumbdrives. Maybe it doesn't understand them; they're supposed to be driverless but the laptop asks for the driver, anyway. New laptop, no problems.

I have several brands of USB 1.1 and 2.0 memory modules which work fine on either my old or new computers, with a transfer speed difference, of course. I have a couple of USB hubs and they seem to work fine, too. One computer does warn if I'm using a high speed device on a low speed port, but it goes ahead and works as soon as I close the warning.

Which is better?
As already said, just depends on what you are looking for. One thing
about these two antennas is that one is a 1/2 wave, the other a 5/8
wave. They have different radiation patterns/characteristic. So,
which of those characteristics would 'fit' your requirements the
best? That's the one that's best for -your- situation.

Win98 needs drivers installed for any USB device. That was the one thing that pushed my into Win XP. Win XP has generic drivers for most common USB devices.

There is no difference between USB 1.0 and USB 2.0 cables.

I'm currently building a 5/8 wave ground plan for 2mx as a tower based
antenna, I have used J pole and slim jim type antennas in the past for the
same purpose with success. I would think that the 5/8 radiator may have
slight gain advantage, but believe that the J pole may have a slightly lower
angle of radiation. The J pole is certainly easier to construct as there is
a bit of mucking about with 1/8wave loading coil on the 5/8 antenna.
There has been much discussion about common mode currents produced on the
feed line for the J pole that can create an unpredictable radiation pattern
which is partly why I'm constructing the 5/8 and partly I'm building a 5/8
ground plan as I have never built one before.

Build both and compare.

If the antenna is for mobile I would certainly use the 5/8 antenna.

K1TTT
> just wind a coil choke

Richard
> What do you REALLY want?

There is a difference between a 12:1 and a 3:1 mismatch, especially in a long coax run. What I want is a rough mid-of-the-range estimate of where impedance in a 50'+50' squat inverted-V dipole across say 3-20MHz.

There is a gazillion description of such antennas fed via 450 ohm ladder lines, and a few with 600 ohm lines:
- ready made 450 ohm plastic clad line is commercially available
- 600 ohm line can be made with commercially available spacers for standard wire gauges.

Neither suggests that the corresponding impedance is a good midpoint. The advantage of ladder lines is extremely low loss, allowing for massive mismatches without much loss due to the exponentially-decreasing but still substantial backwave.

Being forced to use a coax, I am looking for a ballpark match not inspired by the current commercial availability of things I am not going to include in the design.

The random dipole and the T2FD and related antennas (like the ubiquitous 3-wire damped dipole sold by many companies for professional use) are operationally somewhat similar. All are compromise antennas usable in a large spectrum, all are rather funny in terms of losses, radiation efficiency, and radiation pattern.

The damping resistor is there exclusively to smooth the response over the spectrum, at a cost. One could even argue that a balun+coax fed tuned random dipole and an untuned T2FD of roughly similar size exhibit similar losses, ^cept one heats the coax more (once the ATU is peaked), and the other heats the resistor more, which should be handy in determining deicing strategies. ;-)

There is plenty of literature, including some baseline simulations, for the T2FD etc.. I haven't found the same for inverted-V random dipoles. Any pointers? Have I been googling for the wrong things?

Thank you K1TTT and Jim.

I am not going to swap the whole line for a self-supporting type with steel wire in it. I have plenty of spare coax at the low end to cut out the potentially crushed bit and just shift it up.

K1TTT: yes, you correctly point out that the goal is to avoid undue stress, and the last several yards can be left hanging.
Iterating back, the simplest trick of all will be to
- pull it up much of the way
- tape it to the steel rope in at least 3-4 points by taping them together for at least a couple of feet
- let the span between two tiepoints hang somewhat loose.

Thanks again!

If you are going to feed the dipole with coax, there is no balun ratio that would work over the whole range. I would say the best you can do is make it into the G5RV type antenna if 100 feet is about all you have to work with. I do not like the G5RV antennas, but for those that must make a big compromise system, it is one way to go.
If you must use coax, you may also want to look at getting some of the highest impedance coax you can find. Around 100 ohms if you can find any. Then feed the antenna with two runs of it. I am thinking that you just use the center conductors hooked to the dipole ends. Then treat it like open wire and feed it with a tuner.

I would not say any of the simple veticals are better. While I have not tried them from fixed locations, expirimenting with several differant mobile antennas over the years it seems that one type is not really that much beter than another.

Depending on the direction and height of the repeaters almost any antenna can be better going into one repeater and worse going to another. Several of us got together and put several antennas (one at a time) on the same mount of a car. Depending on the particular repeater, there was not one overall winner. The car also had a 40 meter loaded whip that we tried and it was actually better into some of the repeaters.

About the only antenna overall not suited was a colinear about 6 feet long. It worked well enough while parked, but at highway speeds it whipped around so much the mobile flutter made it almost unusable.

I humbly and apologetically decline to comment and, hereby, of course,
deviously venture obliquously to imply that the customary norm of duly
perusing an interrogative ponderation, previously consigned to a
written medium of unrestricted admittance, ahead of proffering a reply
thereto, which in turn will be inscribed for posterity to gape at,
cannot wantonly be construed to be peculiarly fraught with some
unnamed yet capital order of detriment. :-)

While out and about beware of your DC-AC inverter if you have one. If hear whistles and hum, it might come from your own DC-AC inverter. All my AC stuff (PC, cell chargers) is strictly inside the car, so not much noise escapes and even longwave is clear and quiet (I am in Europe). If you have that problem, move antenna and other electric stuff away from each other.

The AOR7030 has a high impedance wire antenna input. If you're really fireside, not easy to beat a random wire, and not even a terribly long one. I wouldn't bother with more than 30-50'.

Just don't trip in the power cord under the moonlight. That radio needs external power, 12Vdc from a vehicle is fine.

You'll have great fun, I envy you a bit.

If you have an oscilloscope, a pulse generator and a calculator you have
a TDR.

If you don't have a pulse generator it takes about 2 IC's to build one.

To give some context with my own experience "in the wild" of South
Africa Zulu/Natal (actually at a 5 star safari camp), I took the
cheapest digital SW radio I could find at Radio Shack, 20 feet of
wire-wrap wire, and connected an alligator clip to the wire so that I
could then connect the wire to the whip antenna.

Without the wire, reception was limited to the hum-drum of BBC, VOA,
DW - with the wire thrown up over a rafter the number of signals were
considerable. I've always considered it underwhelming to get a
distant station playing an American music program like Lady Gaga when
what I wanted to hear was Fela Kuti.

Dear Group: Ian's announcement that he was making a presentation in England, where license exam was also to take place, almost had me flying over the pond. I had a G5 license long ago. We have all benefited by Ian providing a copy of his "slides."

I was convinced to evaluate the AIM4170C and have found it to be delightful and useful. We have a very fine HP instrument in the lab, but it is not easy to use. We dare not turn it loose to be used by our smart, capable students because of its complexity. The AIM4170C not only displays Z, but has a mode of operation that one could teach in ten minutes to just about anyone. The tricky bits are passed off to a general-purpose computer.

Of special interest to me - and distant from antennas - is the built-in capability fully to characterize quartz crystals. I had been using a SG, frequency-counter, and phase meter to gather the needed data and a good HP calculator to calculate parameters. With the AIM4170C one just tells the expected series resonant frequency.

I too have no commercial ties to this instrument.

73, Mac N8TT

4752. Lightning Question

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-09 19:41:49 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <ibc860epv1@news.eternal-september.org>
Source record: 6652

Hello,

Took the plunge, and purchased a WinRadio Excalibur SDR receiver.
I would like to protect it as best I can.

I do receiving only (<30 MHz), and have an end-fed antenna from PAR outside.
We get a fair amount of lightning in the area, but have never had any
direct hits.

I have the typical ICE lighning arrester at the junction (outside) where
the antenna joins the coax leading to my radio in a room upstairs.
The arrester is connected to a ground rod that I laborously banged into
the soil.

What concerns me most I think is the voltage being induced, possibly, by
nearby strikes.
If anything actually hits the arrester, I doubt that it, or anything,
would survive. Probably more of a "feel-good" kinda thing than anything.

So, let me ask please.

a. Can "nearby" strikes, say 1/8 or 1/4 mile away actually induce
meaningful voltages in the antenna (about 10 feet above the ground,
running horizontally) ? How large ?

b. I try, but I am not always home, or remember always to do so
frankly, to disconnect the antenna when done using the radio. Having my
son do it if I am not around is an exercise in futility.

What kind of "protector" can I put right at the radio to try to protect
against any voltage surges (not direct hits) ?

c. What about voltage surges coming in via the AC line ?

d. What about static (buildup) charge ?

e. I've rfead about the Polyphaser line of gadgets. Is one of these
what I possibly want ? They are quite pricey.

I've also read about using neons back to back, and 10 meg ohn resistors,
etc.
Seems to be a lost of cons to this approach, as well as possible
benefits. Thoughts on ?

Any thoughts on all of this would be most appreciated.

Thanks,
Bob

> on the 5/8 antenna.

Why do you call it a 1/8 wave loading coil? It wouldn't be along the lines of the flawed "loading coil replaces the missing degrees" concept would it?

A 5/8 monopole's performance is quite senstive to the ground plane implementation. The behavior of a 5/8 monopole over a perfect ground is not replicated over real radial systems or car roofs, yet people compare antennas based on the perfect ground plane environment.

As the length of the radiator is increased beyone a half wave, low angle gain increaeses until about 0.6 wavelengths when power is shifted into a developing upper lobe. The optimum length over a perfect ground is probably just a little less than 5/8, and less still over practical ground planes.

The other dimension is feedpoint impedance. For a simple series L matching arrangement, R is a little high and the optimum length is typically longer than 5/8.

So, for optimum pattern, and low VSWR, a better solution is a tapped base coil with 0.6 wavelength vertical... but that doesn't play well with the simplest of mobile antenna bases that provide only one connection to the screw on antenna.

Yes.. Some of the voltage is induced because of currents flowing in the
ground, by the way.

The vast majority of power and phone line transients are produced by
induced currents, not direct hits.

Put your protection where the wire enters the house. Lots of UL listed
"antenna protection devices" around, use one of them.

>
> c. What about voltage surges coming in via the AC line ?

Not likely to kill your radio, but a whole house transient protector, at the service entrance, is the best way to deal with it. These days, your power company may offer it for a very nominal fee (dollar a month sort of thing)

>
> d. What about static (buildup) charge ?

This is an issue if the antenna is totally insulated from ground. A high value resistor or inductor to ground will discharge the static from blowing rain, dust, snow, etc.

> would it?

Of course, the loading coil doesn't replace all of the missing
degrees, but it does replace some of the missing degrees. The
following inductance calculator will give the Z0 and axial propagation
factor of a coil from which the VF of the coil can be calculated. When
one knows the Z0 and VF of the coil, it can simply be treated as a
transmission line.

http://hamwaves.com/antennas/inductance.html

It is obvious that the loading coil at the bottom of a 5/8WL antenna
somehow causes the antenna to be electrically 3/4WL (270 degrees) long
because that's the only way the reflected wave can arrive back at the
feedpoint in phase with the forward wave in order to give a resistive
feedpoint impedance. So we need to answer the question of exactly
where those delays and phase shifts occur. Here's a conceptual model
of the 5/8WL base-loaded antenna. (The 50 ohm tapped point on the coil
has been ignored to simplify the problem.)

FP-//////////-----------5/8WL-------------------

(1) The coil occupies a certain number of degrees of the antenna. (2)
Since the Z0 of the coil and the Z0 of the whip are different, there
is a phase shift at the junction of the coil and the whip that can be
easily calculated. (3) The 5/8WL whip obviously occupies 225 degrees
of the antenna. All we have to do is figure out what the phase shift
is at the coil/whip junction and how many degrees the coil occupies.

degrees of coil = 270 - 225 - coil/whip phase shift

There's no magical faster-than-light propagation through the coil as
predicted by the lumped-circuit model. Coils are known to cause a
delay and the Hamwaves inductance calculator provides us an easy way
of calculating that delay through the loading coil. I can provide an
example if necessary.

This has the potential (pun intended) to be the source (pun intended)
of considerable grief. An isolated ground (not connected to the
service ground as mandated by code) will lift during a strike and the
current at that point will seek the better ground by going through
your equipment - NOT pretty.

>a. Can "nearby" strikes, say 1/8 or 1/4 mile away actually induce
>meaningful voltages in the antenna (about 10 feet above the ground,
>running horizontally) ? How large ?

You can get killer potentials on a summer's day with full sunlight and
blue skies. It comes from the accumulated charge carried by particles
in the air. As you describe your antenna as "end fed" and it is
feeding a "high resistance front end"; you are guaranteed high voltage
- n'est pas?

>What kind of "protector" can I put right at the radio to try to protect
>against any voltage surges (not direct hits) ?

Put a 50 Ohm to 5KOhm resistor across the antenna terminals at least
and let the rest of the (properly implemented) protection you
described from polyphaser do its own work.

Better yet, ground the antenna and couple to it through a gamma feed
(or delta match) or direct connect to a folded monopole.

>I've also read about using neons back to back, and 10 meg ohn resistors,
>etc.

You've done some lousy reading if the neons are back-to-back (they
have no "back" to be back-to-back). Neon bulbs in such a described
configuration are ADDING the potential where you are trying to REDUCE
it. What you describe is DOUBLING and GUARANTEEING the frontend
lethal potential. You may as well plug your antenna connector into
the AC socket.

Now, having said that, neon bulbs have a classical application in the
Collins R-390 (I know, because I used to teach the R-390 in the Navy);
and I know full-well that the frontend there was a tube, not a Bipolar
transistor nor a FET. This sort of creates the imprimatur of a magic

amulet that should be hung everywhere....

Another practice was Zener diodes reversed in parallel (the correct topology of your poor reading source for neon bulbs) - which also guarantee lethal potentials, or massive intermodulation problems in the normal day-to-day use of your receiver. Looks good on paper - but IFF you have a tuned front end (as was the R-390 in three stages) and you don't (almost no radios are).

You would need an extremely fast rise-time pulse generator and an
exceptionally fast oscilloscope to match a typical commercial TDR. The
Tek 1502 unit I used when at Eastman's Research Labs had a pulse
rise-time of 140 picoseconds, and the internal display was a sampling
scope with a bandwidth of over
3 GHz. I now have a Tek 1S2 plug-in for my Tek 585A oscilloscope at
home. It's fine for amateur use, but don't expect to see the tiny
impedance "burbles" of BNC connectors with it. {And carrying around a
1502 is _FAR_ easier than the 585!}

Quoting from a Tektronix application note on TDR resolution:
"the resolution limit " wherein two discontinuities or changes on the
transmission line " begin to merge together " Per this definition, the
resolution limit is: half the " 10% to 90% risetime or 90% to 10% fall
time (depending on whether the TDR response is calibrated with a short or
open circuit)."
To convert this to distance, you need to know the velocity factor for the
cable you are testing and the speed of light.

Your installers may not always carry a TDR with them, but I would bet
they have access to one.

Yeah but in the real world you don't usually need to match a commercial
TDR to find a fault.

Back in the days of ethernet over RG-58 I was able to find lots of poorly
attached connectors and cables crushed by the electricians that installed
them (there were no network engineers and installers in those days) with
a 100 MHz 'scope and a pulse generator made from a 555 timer and a 50 Ohm
line driver.

The accuracy of the measurement for fault finding doesn't need to be much
better than a few feet to be able to find the fault visually once you know
about where it is and faults at the end are immediately obvious.

If the task is to find faults, a 'scope and simple pulse generator works
just fine.

If the task is to certify 6 inches of hard line to GHz to some mil-spec, you
probably want something more sophisticated.

Which, is something you would have to spend money on - most assuredly.

OR

Use a wide field microscope against the CRT being driven at the
deflection plates (the early design for these applications of
extremely fast pulse measurements) which can be far more affordable.

Dear Richard,

My question is very simple:

> I'd cut a dipole of about 15 + 15 m (50+50 ft), 120 deg. inverted V,
> apex at 15 m.
> I could do 1:4 -> 300 ohm or 1:9 -> 625 ohm.
> What would be the least-bad?

If you can't or won't tell if such an antenna very roughly better
matches a 300 or 600+ ohm source over the HF spectrum,, what else
can I do but
- turn on EZNEC and start playing
- build two or more transformers and send someone up at the 50ft apex
and swap them in sequence while I do in vivo comparisons and pollute
the spectrum
- wait for someone else to answer or to point me to a good URI?

I can live with it.

I might also put together the rather long list of authors of articles
on the subject and ask them on your behalf what they really really
want if they have to feed the thing with a coax instead of ladder
lines of the commercially available impedances and want the least
lossy solution among the available alternatives. :-)

On Nov 9, 6:39 pm, Cecil Moore <w5...@hotmail.com> wrote:
> ... the Hamwaves inductance calculator provides us an easy way
> of calculating that delay through the loading coil.

http://hamwaves.com/antennas/inductance.html

Assume a 10" long, 100 turn coil with a diameter of 2" wound with #18 wire. In metric, that's 254 mm long, 50.8 mm diameter, and 1.024 mm wire. At 4 MHz, the above calculator indicates that the axial propagation factor is 2.122 rad/m which we can convert to degrees/inch by multiplying by 1.4554 which yields 3.088 degrees per inch. The coil is 10 inches long so the number of degrees occupied by the coil at 4 MHz is 30.9 degrees.

If this coil is used as a base loading coil in a 4 MHz mobile antenna, it occupies ~30.9 degrees of the antenna. A 7 foot whip occupies ~10.2 degrees at 4 MHz. The antenna, at resonance, is known to be 90 degrees long. So the phase shift at the coil to whip junction has to be ~48.9 degrees assuming resonance at 4 MHz.

For an electrical 1/4WL base-loaded antenna, e.g. an HF mobile antenna, there exist three phase shifts that add up to 90 degrees. The phase shift through the coil plus the coil to whip junction phase shift plus the phase shift through the whip have to add up to 90 degrees. For a center-loaded antenna, there are four phase shifts that must add up to 90 degrees. The phase shift at the base to bottom of loading coil junction is negative. That's why we need more inductance, i.e. more phase shift, in the center-loading coil than we do in the base loading coil.

If we are dealing with a 5/8WL (225 deg) antenna, the phase shift through the base coil plus the phase shift at the coil to whip junction must add up to 45 degrees such that 225 deg + 45 deg = 270 deg = 6/8WL.

Can you detect where RG-58 was kinked and then straightened out with the damaged area being less than 1/2 inch? Likewise can you detect an abraded shield leaving a 1/4 inch hole in the shielding?

An LM555 has a rise and fall time of 100 nanoseconds. I have no idea of how much your line driver sharpens the edges of the pulse, but a good line driver should provide rise and fall times of 5 nanoseconds. The original TEK 1502 at 140 picoseconds can resolve to about 2 centimeters. With a risetime of 5 nS, your resolution will be about 70 times worse (140 cm). Add to this the 100 MHz limitation of the scope (an additional 10 nS), and it becomes far worse.

Yes, you can easily detect shorts and open circuits with your setup, but you will not be able to detect the 1 to 2 inches or so where the center conductor has migrated in the foamed dielectric from hanging the cable over a building edge.

The kind of fault Spamhog originally described, a 75 ohm cable dropping to less than 50 ohms over two inches and going back to 75 ohms, will not be detected by your setup.

I was able to detect where cables were squashed by overly tight bundle lacing
and bending over a short radius.

It got me close enough that a visual inspection of a few feet found the
"bad" place.

> An LM555 has a rise and fall time of 100 nanoseconds. I have no idea of

> 10 nS), and it becomes far worse.

Like I said, if you have a pair of eyes, all you have to do is get close.

And in any case, the solution for a cable run that is hosed somewhere in
the middle is to replace the entire section. Cutting a section out and
putting in connectors to splice the cable is just asking for more problems.

> Yes, you can easily detect shorts and open circuits with your setup, but

Yet I could, so either I'm a lier or you are overestimating how hard it
is in the real world.

It would detect that there was an impedance lump.

It would not tell you it was a 50 Ohm lump.

>- turn on EZNEC and start playing

You keep repeating what you have. Can't or won't telling is still a
matter of

What do you really want?

You are forcing this into my trying to read between the lines and
guessing, so here goes:

- in spite of demurring about
>> no pretense to have perfect match
>>or minimum losses.
You "want" something with a near-perfect match and near-minimum losses
"over the HF spectrum."

This is dreaming in technicolor and 5.1 Dolby sound.

This is a technical forum and the expectation is that you provide a
range of acceptable match and a range of acceptable loss enumerated by
the frequencies of interest. You show no concern for directionality
which will be wildly variable. In other words, something quantifiable
is needed or you are doomed to inaccurate response or tedious
instruction (such as mine). Qualified statements are suited only for
cheap sales brochures.

To your credit, you enumerate the particulars of your antenna and to some extent the working band: 3MHz to 30MHz. However, even on first glance, such an antenna is NOT suited for covering the entire HF region. This should have been a minimum observation in your readings, and the absence of its discussion by you means you either have poor sources, or you are prepared to abandon this antenna's use on some bands (do your sources tell you were it is going to fail miserably?). The use of BalUns is not a solution to this and the solution, such as it is with a Hi-Z resonator, forces problems into the other bands. This too should be a minimum observation available from your reading material.

>I might also put together the rather long list of authors of articles
>on the subject and ask them on your behalf what they really really
>want if they have to feed the thing with a coax instead of ladder
>lines of the commercially available impedances and want the least
>lossy solution among the available alternatives. :-)

Try googling the terms "wide band" "hf antenna" and writing to the 2,960 authors.

This board is innundated with claims and testimonials to those designs all the time - such freely available "articles" do not constitute evidence nor bring legitimacy.

There is one very simple, logical test for the answer to your unstated question - if you can't buy or find one, why do you think it exists or can be so easily assembled?

Owen, I think the popularity of VHF mobile 5/8 antenna lies in it has more gain than a 1/4 wl antenna and is easier to match to 50 ohms than a .5 wl antenna. I had certainly rather DIY a 2M 5/8 mobile antenna than a .5 wl version. From information I have seen the 5/8 often touted for its low angle of radiation may actually have a significantly higher angle of radiation than the .5 wl antenna used in a similar situation. This is not to say either antenna would not be equally useful.

Hello,
I have just built a J pole antenna for the local our local Emergency Service centred on 410 Mhz for their field/portable use.

I note that the Arrow antenna feeds the 1/4 w/l element directly, but the standard J pole feed is on each element.

What works best? The standard J pole feed or the way Arrow feeds theirs?

Cheers John

Are you telling all the rest of us that may have inferior equipment that
we shouldn't even try to measure things?

Just asking.

And we aren't all dumb enough not to understand what gives us resolution.

I could reply as one here does and say -

YES

And then he would leave it there and scold you for not knowing how.

Neither feed is superior. The issue you need to address is that this is
a balanced antenna fed by an unbalanced feedline.

So your mission is to lessen the current on the outside of the coax.
This involves a choke, which could be ferrite based or coiling the thing
up based. I won't get into it beyond this since it's all out there with
google search and google news search.

Arrow feeds their "J-Pole" like a Zepp antenna through a 1/4WL series
section. The spacing of the antenna elements are such that a 50 ohm
feedpoint impedance results. The standard J-Pole uses a shorted 1/4WL
stub for matching. The stub is tapped at the 50 ohm feedpoint
impedance. There is hardly any difference in the two designs.

Jim,

I think you need to go back and read Spamhog's original question. He was trying to determine whether the center conductor of a piece of coax had migrated away from center. He knew where this might have happened - 10 feet from the end, and the migration would have occurred over less than two inches. So the question of locating where the problem might be is moot. What is needed is a measurement of the cable impedance in this region.

First, let us get an estimate of what the impedance of the damaged section might be. Spamhog was using RG-6 cable with a foamed polyethylene dielectric. Its velocity factor is 0.85 making its relative permittivity 1.384. The center conductor is 1 mm, and the normal diameter of the center insulator is 4.7 mm. The thickness of the insulator is 1.85 mm. We need to know the impedance if the center conductor had migrated 0.925 mm toward the jacket.

For a quick estimate, use the formula for off-center coax (http://www.microwaves101.com/encyclopedia/coax_offcenter.cfm). This gives an impedance of 69.8 ohms in this section compared to 78.9 ohms in the non-distorted coax. A TDR displays the reflection coefficient from -1 (short) to +1 (open). Here the reflection coefficient is -0.06. So the TDR trace will drop from the center line by 6% for 200 picoseconds.

If your 100 MHz scope has a typical Gaussian response, its rise time is at least 3.5 nanoseconds. Do you really think that your oscilloscope trace will clearly show the 200 picosecond dip? Even with the wide-screen magnifier that KB7QHC suggested, I think you will have great difficulty seeing this.

No. In fact, playing with a scope and a pulse generator is quite
educational.

> And we aren't all dumb enough not to understand what gives us
> resolution.
>
> tom
> K0TAR

Trying to measure the thickness of a single sheet of paper with a ruler
graduated in eighth's of an inch is analogous. About all you can say
with certainty is that the paper is much thinner than 1/8 inch.

My last post gave a nominal value for the reflection coefficient of coax
with a migrated center conductor like N1PR postulated. At 2 GHz, the
2-inch section will be about 0.4 wavelength. Will you get detectible
reflections? Yes.

> 73, Barry WA4VZQ

The bandwidth of the 'scope will make the trace have a ripple intead of
the nice, sharp bump you would get from a faster 'scope.

Spamhog's original statement was that the cable was crushed to half diameter
for about 2 inches as I recall.

I was able to see ripples in the display for cables with less crush then
that which were on the order of 1/4 wide.

The bottom line is the faster the 'scope you use and the faster the rise time of the applied pulse, the better the meaurement.

And since this is a hobby and not building man rated space craft, I would say try whatever you can get your hands on for free and see what happens.

Or spend eternity arguing whether or not it is possible to do.

Thanks Tom,
Yes I am aware of the balanced/unbalanced feedline, and have coiled the
feedline directly below the antenna, and have done my share of Googling!

But what I want to know is how the Arrow manages to match the antenna to the
50 ohm feed.

I am thinking its in the spacing of the two elements?

Cheers
VK2KC

feedpoint impedance results. The standard J-Pole uses a shorted 1/4WL
stub for matching. The stub is tapped at the 50 ohm feedpoint
impedance. There is hardly any difference in the two designs.

Hi OM,

Both styles are the same basic method. You are using a length of
transmission line (the paired section) to match one Z to another Z.
The line Z is part of the equation (the spacing, as you asked).

One method (most observed) uses a tapped feed which for the shorted
section is located at the line's translation to 50 Ohms, the open end
is a higher Z matching to the half-wave radiator (I won't go into the
difficulties and considerations of the matching section also
radiating).

The mystery feed point (do I connect my "hot" lead to the long wire,
or the short one?), its magic position, all contribute to a religious
lockstep of praise. In itself, it has virtually nothing to offer but
complexity.

The other method (infrequently observed) simply approaches the
situation in the classic application of a line transformer. Think of
the smith chart. It's amazing how often this method is used at HF,
but draws blank stares when we shift to UHF.

I have built, measured, and tested antennas employing the second
method because, frankly, it is far simpler to construct on a SO-239
connector: one wire in the center conductor, one wire from any of the
four holes - end of story (neglecting the precautionary tales of
decoupling everything).

The practical side of this home-brew is you build one "close enough,"
and then with the aid of a SWR meter, you clip off 1/8th inch portions
of wire (either side until you get the drift of it) until you have
flattened it out the pesky SWR - and then walk away.

Anyone versed in using the Smith Chart will immediately recognize that
there are many possible satisfactory solutions. As is common with
cautioning children not to run with scissors, not all Z-match
solutions are preferred radiators.

The free version of EZNEC is eminently suited to exploring this.

It depends on the vehicle and mount location.
I think often a vehicle provides a better lower section
than the usual ground plane with 1/4 WL elements.
I've seen 5/8 whips do quite well on vehicles if they
are mounted in a good location, the best being the
center of the roof. They beat 1/4 WL whips in comparison
tests, and often showed less "picket fencing".
I imagine a 1/2 wave would work well, but I've never
actually tried a 1/2 wave whip on a vehicle due to
it generally being more complex to build and match.
And in the end, I think the 5/8 would probably beat it
anyway.

But in another comparison on 10m, the elevated
5/8 GP's beat the elevated 1/2 wave's I tried.
And all were decoupled from the feed line.
The comparisons were done locally, using the
space/ground wave which is low angle critical,
and the 5/8's always won to stations that were 30-40
miles away vs the 1/2 wave's.

Anyway, I'm not nearly as negative about 5/8 wave
antennas as many people are.
But like I say, I think the 5/8 over 1/4 wave GP scheme
is perverted and can be greatly improved using more
sane designs. :/

The maximum gain for a single element is .64 wave.
And that gain is usually considered appx 3 db better
than a 1/4 wave. But if I remember right, the dual 5/8
collinear is usually rated at about 3 db better than a
vertical 1/2 wave. "appx 5.1 dbi".
For VHF/UHF use, the old AEA Isopoles were one
of the best commercial verticals built as far as gain
and decoupling of the feed line. Those were dual 5/8
designs with lower decoupling cones.
It was the superior decoupling that really made them
shine at low angles.

Well not exactly, IF, one were to take a "Stack" of said paper, that was
exactly 1/8 of an Inch thick, then count the number of sheets, and
divide the 1/8 inch by the number of sheets, One could get a VERY close
approximation of the thickness of a single sheet..... Duh...

I ve had both .5 and .64 wl antennas on my big Chevy Van. I cant tell
any significant difference in performance except for a couple of .5
antennas that were really poor performers, I think this may have been
due to matching network design.. Except for this cause I dont see how
there could be any perceptable difference in the two antennas short of

careful measurements on an antenna range..

Note that I said the thickness of a _single_ sheet. Your method would give an approximation of the average thickness of the sheets used to make up the stack. But if you have ever worked with a Fourdriner machine that is not controlled well, i.e. the thickness varies with time due to any number of variables, you would need to know the thickness of a number of individual sheets to determine which variable is causing problems. Typical variables that would cause the thickness of a sheet to vary include, but are not limited to, head box level, "wire" speed, pulp "consistency", felt pressure, calendar pressure, the type of wood used, the lignin removal process (Kraft, caustic, or solvent), Crown Control pressure, drying roll steam pressure, and at least a dozen more. For example, sloshing or waves in the head box would cause thickness variations in both the machine and cross direction, while "wire" speed would only cause thickness variations in the machine direction. So there are real reasons for measuring the thickness of a single sheet.

Just as Richard has constructed several, so have I. I made a somewhat frequency adjustable one for a friend that does audio for car shows here in the Minneapolis area. He has dozens of remote speakers that run on commercial RF distribution freqs, but also transmits low power FM broadcast for those cruising the show. I used a base length for the 2 rods for the high end of the band plus 1 tip for the quarter wave section and 2 for the 3/4 wave section. Gave him a chart that showed what combinations covered what frequencies with roughly 1.5 to 1 or better SWR. Works like a champ. used a simple 7 turn on 1.5 inch PVC choke to _reduce_ feedline radiation. Told him he might want more, but up to him.

Scaling the Arrow design to around 100 MHz involved increasing the spacing between the 2 rods, as you might have suspected. The design using changable/removable tips works, but the bandwidth got narrower towards either end of the US FM band.

It has been about 30 years ago, but I remember that while Kappa is related to the amount of lignin remaining in the pulp after cooking, every wet end process had its own peculiar measurement. I worked on the online measurement of Kappa for several solvent pulping processes that were to produce dissolving pulp for Eastman's cellulose ester process. Once the vendor that supplied our pulp got wind that we were researching solvent pulping, they quickly dropped their price and raised their quality enough that we halted work on our own pulping processes. One process we were considering involved the use of supercritical CO2. We never got beyond early pilot plant work on this.

I fully understand the {sic} in your statement.

> When it gets down to what you describe as "not controlled well" that

I have toured quite a few paper mills over the years with both Kraft and caustic pulping. I never really got to see one of the large continuous digesters though. We had a small caustic plant that used hardwoods in town with us. The odors were interesting - mercaptans by them and the occasional butyric acid spill by us.

I always wonder how long the cellulose acetate business will last. While cigarette smoking is declining in the US, increasing demand from China seems to more than make up for the loss.

Going back to the original TDR discussion, probably the most interesting use I ever put one through was in diagnosing thermocouple problems in our coal gasifier. I saw that the platinum-rhodium thermocouples had water in them. We finally got a metallurgist to do an "autopsy" on one of the thermocouples pulled out during a shutdown. When we broke open the

thermocouple, water ran out. We saw a buildup of salts from the Saureisen cement at exactly the place that I predicted. Water was diffusing in through a silicon carbide protection tube and an Inconel sheath.
Of course the gasifier operated at high temperature and pressure. A Nastran simulation of the thermowell showed that the temperature at that point was low enough for condensation to occur. Some extra insulation on the external flange solved that problem!

If that means the lore of paper processing, I was peripherally involved in trying to characterize Black Liquor (http://en.wikipedia.org/wiki/Black_liquor). Gladly I was at the extreme periphery (I am sure my sense of smell was debilitated in those years).

However, returning to things RF, I also was tasked with calibrating a wood moisture meter. It used an HF RF source as part of a Z meter were Z was correlated to moisture content. The probe was a fixed ring surrounding point probes much like a Kelvin Bridge. It has always seemed paradoxical that steam is used to dry wood.

Now, finding calibrated wood was no easy task. And if we found it, we would have to first validate it (sort of a circular form of Sysphus' task). My best guess at that work set to us was that we gun-decked it.

It was some years later that that task came around again when I was measuring K and Kappa as I averred. Here came the requirment for "Bone Dry" paper. Try as you might to dry paper bone dry (absolutely no water content), that as soon as it comes out of the oven it is almost back up to several percent water content (15% to 20% would be the end point).

Ironies compound in that I now live in a community where 100 years ago our cedar wood mills produced nearly a Billion shingles in a year.

After I could not stand the Fiesta any longer I ordered a new Cadillac
Cimarron. I did not want to drill any holes in the new Caddy so I
bought one of the thru the glass end fed whips. Its performance was OK
and it did not draw attention to the vehicle so I lived with it.
130,000 miles later it went to our son radio, antenna and all! It only
made sense when he was licensed. If I were doing it again I would have
drilled the appropriated hole in the roof above the dome light and
installed a Larsen 2m & 400 antenna. That was the last time I
hesitated about drilling a hole where I needed it.

Now that I am in a 2008 Chrysler Minivan I have taken the lazy way out
and placed a mag mount quarter wave on the luggage rack (no scratching
there) with the coax ty-wrapped to the rack so there is not enough
slack to allow real damage if it gets knocked off. An itty-bitty Yaesu
FT-90 sits on a sticky pad on the dash and plugs into one of the
vehicles many12v power outlets. The power outlets are not like the
cigarette lighters of the past. They are well installed and fused at
20 amps. As long as you purchase a plug to handle the power and trim
the cable to what is necessary all is well.

The FT-90 gets too hot to handle and shuts down on lengthy rag chews at full power, but does fine at lower power settings.

You can waste a lot of time and money over killing a mobile antenna for repeater operation. If you are out in the wide open spaces, maybe it is worth it!

I once had to check on an instrument I had designed that was used in our cellulose acetate butyrate esterification area. (Cellulose Acetate Butyrate is used to make Xelite and Craftsman tool handles.) Acetic anhydride and butyric acid were used for esterification. For those not familiar with the odor, think of a mixture of rancid butter, vomit, and the contents of a cat's week old litter box. Readers who watched the last season of Whale Wars on TV saw it being used against the Japanese whaling ship and its cargo.

Since I was unfamiliar with the building, one of my technicians who had installed the instrument went with me. We stepped off the elevator and walked into the processing area. What had been an extremely offensive odor in the elevator suddenly hit me like a ton of bricks. I couldn't see as my eyes were tearing badly, and it hurt to breathe. My tech told me to stand still for a moment or two and things would get better. Within thirty seconds to a minute, my eyes cleared up, my sinuses opened up, and my breathing became normal again. I could no longer smell the mixed acids at all. We checked the calibration of the instrument and talked to the operators about their experiences in using it.

We then left the building and walked the half mile back to the research labs. Eastman was still using dimethyl-terephthalate in their polyester production at that time, and as I waked past the DMT distillation area, I could easily smell the DMT and the Dowtherm heat transfer fluid. My technician explained that as soon as we returned to the research complex, we should drop by our group leader's office to let him know where we had been. We had just opened his door when he said that he could smell where we had been and to get the heck out of his office! Of course, we couldn't smell our strong odor at all.

Fortunately my technician had warned me to wear old clothes, old shoes, and an old belt for when I came home that evening, my wife made me strip in the foyer and go stright to the shower. She washed the clothes, but the shoes and belt had to hang outside for a week. It seems that leather is particularly bad about absorbing the odor.

We used microwave absorption to measure moisture in cellulose acetate filter tow (cigarette filters are made from this). Operators would cut off a length of tow and stuff a weighed amount in a short X-band waveguide. Attenuation was proportional to moisture.

> Now, finding calibrated wood was no easy task. And if we found it, we
> would have to first validate it (sort of a circular form of Sysphus'
> task). My best guess at that work set to us was that we gun-decked
> it.

Calibration of the microwave quipment was checked by weekly sending samples to be tested by nuclear magnetic resonance. We also used samples kept in jars over certain salt solutions that maintaned a constant relative humidity in the jar. See http://www.conservationphysics.org/satslt/satsalt.php for some typical solutions. To bring a little electronics into this, the same principle is used in electrolytic capacitors where glycols, sorbitol, and various salts are used in the electrolyte to insure that it remains moist. Electrolytic capacitors are about the only electronic components that are harmed by an exceptionally dry environment.

> the end point).

You can get close to "bone dry" in a sealed container containing zeolite molecular sieves baked at 600 C. But as soon as the container is opened, moisture rushes in from the surround air. We would use glove boxes pressurized slightly with nitrogen obtained from a liquid nitrogen source when we needed a really low humidity environment.

I always enjoyed visiting the University of Washington where Eastman was on the industrial advisory board of the Center for Process Analytical Chemistry. I never order salmon from any restaurant in the southeast after eating the wonderful, fresh-caught salmon you have there!

73, Barry WA4VZQ

P.S. You mentioned black liquor from the Kraft process. I once visited the Glidden-Durkee plant in Jacksonville, FL. They originally produced

turpentine from pine stumps, but now they start with tall oil extracted from black liquor. It is hard to believe that essential oils, perfume stock, and flavorings are all derived from turpentine.

For sale in Collierville, TN and local pick up only is a Motorola TDD6034A VHF vertical collinear antenna that is about 23ft long. The fiberglass is in good shape as I have stored this my garage for years. Pulled it out recently, cleaned, repaired, painted and tested it. Was going to use it but due to our Home Owners Assc. I cannot put it up. Freq range listed on tag is 149-154Mhz. I put my MFJ antenna analyzer on it and at 146Mhz the SWR was about 1.7 to 1, so not to bad! Would make a good repeater antenna. Sold as-is and again local pick up in Collierville, TN only!

> would it?

I referred to the 1/8 wave loading coil without really thinking about it. I was unsure of the loading coil dimensions, so I simple tried a 1/8 wave length wire formed into a coil. This is for the simple series arrangement 5/8 radiator. This created a load coil that appeared to have a little too much L so I have removed one turn, seems to load up ok after a little trimming of the radiator. Keen to hear how too determine the value/dimensions for the loading coil.

Having said that I'm not sure what so wrong with missing degrees" concept.

My current 5/8 wave ground plan project is simply to get something on air, however I plans to construct an improved version with the tapped coil approach.

I may be looking in the wrong places, but I have been surprised at how little information there is on the net regarding 5/8 wave ground plan.

Thanks Owen for the above over view of the 5/8 wave ground plan.

Cheers

:-) Because there are two sides of the argument each at the two
extremes. The technical truth is that the coil does replace a certain
number of degrees of the missing part of the antenna but not all of
the missing degrees. I am preparing a technical article that explains
the details. Please stand by.

Hi Peter,

One theoretical method is to model the antenna, and find the feedpoint impedance. The R component decreases as length increases from a half wave to three quarter wave, and X increases towards zero.

Best pattern is closer to a half wave, but R is very high. At 0.7 wavelengths, R is low enough for an acceptable match by using a series inductor, and reactance will be a few hundred ohms give or take depending on length.

> Having said that I'm not sure what so wrong with missing degrees"
> concept.

For one thing, if a certain inductance is required, the quantity of wire needed depends on several underlying coil parameters.

...
>

That lets you shorten it for a bit more gain, and a good match.

If you cut the vertical for 0.6 wavelengths, you should think of starting with an inductor with reactance towards 1000 ohms.

Probably displaced by OTS 4 band verticals.

Have fun.

I meant to elaborate on this a bit more. (Did I hear someone groan?)

If for example, the feedpoint Z of a 0.6 wave vertical over four quarter wave radials was 150-j500, your tapped coil matching network can be designed using bulk standard circuit theory to transform 150-j500 to 50 +j0, and nowhere do you use the missing 54° in those calcs. That might suggest that the "missing degrees" are some kind of explanatory crutch (or ham speak) that is not directly related to solving the problem.

I'll bite (or groan as the expectation demands) - why "quarter wave"
radials? A rule of thumb?

* * * Rhetorical questions follow * * * *

Quarter wave in physical length?

Quarter wave in electrical length?

Elevated Quarter wave radials?

If elevated, Quarter wave drooped radials?

* * * Philosophical ponderings follow * * * *

The discussion of radials usually attends ground mounted studies in
the 100M band in the 1930s. Those studies sought to reduce loss while
mimicking a conductive ground of infinite extent. Radiators taller
than Quarter wave were treated to feedpoint loading (such as found in
the current topic, albeit with the possibility of it being elevated
and thus muddying the philosophy here). All such historical (and
current AM band engineering) feedpoint loading presumed, basically, a
non-resonant ground system. As Quarter wave long radials imply
resonance (at least in the first read), this would suggest that,
perhaps, this "tuning" should be further examined in light of
feedpoint loading. The conclusion, to my mind, would be that
significant reduction in feedpoint loading could be accomplished by
tailoring radial length (much less drooping that is already part of
the lore).

At first blush, it would seem that the radials would be shorter than
Quarter wave (forgive me for not first confirming this astonishing
leap of faith).

Of course, there is every chance some reactance will remain to be
"tuned" away (returning us once again to loading) - if the mismatch is
deemed significant.

If such is the case, and returning to the original design, what
problem is the Quarter wave length radial rule of thumb responding to?

* * * * Alternative analysis * * * *

Or to put it into the light of other antenna topological discussions, and in this regard the off-center fed dipole. Here we have an off-center feed (we rarely go on to describe all such installations as "vertical dipoles"). We can fully expect that, as such, we are transforming the expected 70ï¿½j0 Ohms into some other value. Quite frequently in an OCF design, it is much higher - and variable by the degree of offset. However, for a fixed frequency, this is better understood and can be anticipated. The proximity to ground and the geometry (the radials certainly disturb the shape of an OCF dipole, even if vertical) further change things, but conceptually the monopole with resonant radials still constitutes an OCF design that is "on center fed" for the vertical element when it, too, is a Quarter wave in length.

For many prospective feed points along the length of the OCF dipole, the only consideration needed is for a ratio transformation, not tuning. This is usually resolved in a BalUn. Hence "loading" is removed from the picture through careful consideration of the whole antenna, the degree of offset, and not through arbitrary assignment of Quarter wave length radials to all vertical designs.

* * * * Conclusion * * * * *

The concept of a loading coil where its length of wire "replaces" the missing length of radiator wire is a commonplace for technologists. It serves the discussion quite well at that level.

The value of this length of wire's inductance is going to vary by significant value for the many coil form variables available to the technician. Hence the exactness of this "replacement" is questionable on the face of it at the engineering level of discussion. This equivalence "replacement" is forced further into unresolved exactness if we move the same coil up into the radiator (without changing the radiator's length).

The same could be said with the treatment of Quarter wave length radials, which, after all, are a special and not general solution.

It is just what I modelled, so I was declaring the context. The thread started on 2m, my discussion was in that context, and the usual application would be elevated radials, I modelled free space.

I used a quarter of the free space wave length. It is not that important because as you note, matching the feedpoint impedance deals with the length issue. The reason I didn't specifiy any slope is that they were horizontal.

Other configurations are possible, but the numbers will vary.

I suggest that as the vertical length approaches a half wave, a set of shorter radials, and perhaps three might well provide adequate decoupling... but Z will differ again.

I was not trying to publish a working design, rather to give some info on the way these things behave.

The way you did it works pretty good. A lot of practical antenna work
is estimate and trim.There is or used to be a site that goes into a
lot of detail on the 5/8ths. I had it in my bookmarks for a long time
but lost it in my last computer crash. Compares 5/8ths with 1/4 wave
radial 5/8 radials horizontal and drooping radials and much more.
Sorry but I cant remember who had the site bet someone here does.

sorry, one more link: http://www.trinasolar.com/pdf/TSL-DA01.pdf
mine are the TSM-DA01 185w panels. so read the right hand column of
the table.

I modeled a few of the usual versions.
http://home.comcast.net/~nm5k/acompari.htm
I had thought I had also modeled a few using resonant
3/4 wave radials, but I guess I had found better modeled
results using the 5/8 radials. But I know the 3/4 wave
radials give a much better pattern than the 1/4 wave
radials, but maybe a tad less gain than 5/8 radials.
But these show why I don't like 1/4 wave radials for
a 5/8 radiator. And Richard may have a point about it
it being an "OCF" antenna. This is why I consider it
perverted. I don't like horizontal OCF antennas either.. :(
Through the years of modeling these, and playing with
them in the real world, I've noticed a few things about
the radials.
I prefer sloping 1/4 wave radials when used with a 1/4
wave radiator. The performance difference between
"straight out" radials is not large, but is about .3 db
or so better with the sloping variety. And you get a
bit better match.
But sloping 1/4 radials with a 5/8 radiator is bad news.
The pattern is even worse than when they are straight out.
So if one were to use 1/4 radials on a 5/8 GP, they should
be straight out for the best results.
But I much prefer using either 3/4 or 5/8 radials with
a 5/8 radiator, and the plots show why.
The pattern is cleaned up, and the high angle lobe
does a vanishing act. You then start to see the
comparative textbook gains at the horizon when comparing

to shorter antennas.
IE: most books will claim a 5/8 antenna to have appx
3 db gain vs the 1/4 wave.
But you won't see that with the short radial version.
The gain is there, but it's not on the horizon where you
want it.
If you look at the azimuth plot for each, note the 1/4 GP
shows about 1.8 dbi, and the 1/2 about 2.1 dbi.
As they should..
But look at the perverted 5/8 version.. A lowly 1.1 dbi
at the horizon, with most of the real gain shooting off
to venus at about 45 degrees.. The antenna is sad, and
needs therapy.. :(Where is the appx 3 dbi we are
supposed to be seeing?
But if you check the version with sloping 5/8 radials,
we see our expected gain on the horizon. About 3.1
dbi in this plot. That's pretty close to the theoretical
expectations.
But if you make the long radials even steeper to
more closely resemble the collinear, the gain increases
to 4.25 dbi.
You are starting to approach the gain territory of the
dual 5/8 collinear which will show about 5.1 dbi on
the horizon. Assuming good decoupling from the
feed line of course... Decoupling is half the battle,
and if it is ignored, one might as well hang a wet
noodle on the roof, and be done with it.
This explains why I have such a negative view of
1/4 wave radials under a 5/8 whip. It's like using
a band aid to deal with severe chainsaw lacerations.
The blood with still spew, and it will be spewing
up into the air at about 45 degrees from the horizon.
Chortle..
All the speculation about matching seems silly to
me. The matching coil is so simple to apply, it's a
non issue. I've built so many of them, I can tell
you about how many turns to use for any particular
band.. I can usually just guess, and get pretty close.
Maybe tweak a turn or two to get just right..
It's simple, and any matching schemes should
not interfere with the lengths of the elements
if you want the most gain at low angles.
It's like matching a yagi.. I don't alter the element
lengths of a yagi to get a batter match. I use the
appropriate matching scheme, and leave the elements
the length they were designed to be for the gain/fb
the antenna was designed to produce.

This is a great thread! Cooperative discussions like this are way too
rare!

As a humble student of the Art, I have come to consider each antenna
as belonging to either a Resonant or a Non-Resonant classification.

While there is no "best solution" to most antenna configurations,
understanding the decisions you make and utilizing the available
resources make a big difference in the outcome.

I hope you guys can keep the thread going for a while, you are
answering questions that I have been unable to ask!

That's because the lumped-circuit model assumes that all signals
travel instantly at faster than light speeds through the coil. At
instant, faster than light speeds, the coil cannot possibly occupy any
degrees of the antenna. When the real-world speed of light limit is
taken into account by using the distributed network model, the degrees
occupied by the coil falls out as part of those real-world
calculations. The lumped-circuit model is simply flawed for the
purpose of trying to determine the degrees occupied by the coil. I am
finishing up an article on this subject. At 3.5 MHz, the velocity
factor of the 100 turn, 10 inch long coil is 0.04, which makes the
coil occupy 26.4 degrees when used for a 3.5 MHz mobile antenna.

The "Axial Propagation Factor" from the Hamwaves Inductance Calculator
at:

http://hamwaves.com/antennas/inductance.html

can be used to determine the number of degrees occupied by a loading
coil. For the above coil at 3.5 MHz, the axial propagation factor is
1.8118 radians/meter. Multiplying by 1.4554 converts it to degrees/
inch. The coil is 10 inches long so: 1.8118(1.4554)(10) = 26.4 degrees
occupied by that loading coil at 3.5 MHz.

We can model a transmission line as lossless, but none exists in
reality.

We can model a loading coil that occupies zero degrees of the antenna,
but none exists in reality.

> radiator's length).

From a conceptual standpoint, there is no "unresolved exactness".
Considering a base-loaded antenna vs a center-loaded antenna:

FP-/////////-y-------------------------------------

FP----------------x-/////////////-y--------------------

The coil used in the center-loaded antenna must occupy more degrees of the antenna because in the center-loaded antenna, the phase shift at the base section to bottom of coil impedance discontinuity at point x is negative. This is obviously true because the characteristic impedance (Z0) of the coil is in the ballpark of a magnitude greater than the characteristic impedance (Z0) of the base section. There is no negative phase shift at the feedpoint of a base-loaded antenna. For the same reason, the phase shift at the top of coil to whip discontinuity at point y is positive.

I am writing an article that conceptually explains it all.

Hi John,

True, this has everything to do with utility.

>I hope you guys can keep the thread going for a while, you are
>answering questions that I have been unable to ask!

It's easier to keep the thread going (productively) if you could choke
up a question.

If I were to rummage for key points in the hopes of doing what you
ask, I could as easily bore you (everyone).

Fishing for just such an example, and returning to both drooping
radials on a 5/8ths and how that might cause this design to suffer
equally with the worst of J-Pole performances, let's look at the
silhouette of the 5/8ths with drooping radials:

Overall, it gives us a radiator that starts out 5/8ths tall (radials
out at 90 deg), or gets "taller" as those radials droop. In the
extreme (radials fallen to 0 deg), we now have a 7/8ths tall radiator
(my aforementioned OCF vertical dipole). Neglecting problems of
feedpoint Z, this radiator lobe pattern could be pushed beyond the two
towards developing four lobes. Without checking this in EZNEC (left
for the student to perform), this could result in transforming an
already higher gain antenna into becoming a cloud warmer.

This (the additional, higher lobes) is often the fate of the J-Pole
when the line that feeds it becomes part of the radiator. We get
glowing reports of how well J-Poles have been built and matched, and
sometimes grief over how deaf they are (How could this be?).

Thanx, that pulls it all together. Not NASA quality, but still pretty
high performance. Have you thought of geothermal? Sitting here
between several dormant-to-active volcanos, and on top of several
faults, the options are numerous here in Rain City. (Cost at roughly
$20K)

not very likely on this coast... i doubt that there has been any active hotspots around here for many millions of years. besides, the feds and state don't give any grants and tax incentives for drilling holes in the ground. if it weren't for the state grant for construction, state cap and tax law that will pay me for my power, and state and federal tax credits, this would not have been economically worth while.

4813. Matching antenna to crystal radio

Newsgroup: rec.radio.amateur.antenna

Hi Guys,
Assuming I have a tank circuit on a crystal radio with a Z at resonance of
1.5 megaohms.
How would I make an antenna and extract maximum signal and keep the Z at
750,000 ohms.
If don't think that's what I want to do, tell me that too. :-)

I have a piece of rope that's also about 23 feet long,
also in good shape. The big difference between your
antenna and my rope is that I won't offer my rope for
sale in a newsgroup that isn't for buying and selling.

Does that mean anything to you, TimBob?

It may be that a 100 MHz scope has better than a 3.5 nsec risetime,
given that it is sped'ed for response flatness to that limit and its
response actually extends beyond !00 MHz. In retirement, I no longer
have access to test equipment that would support my point.

Hi Mike,

Try thinking backwards. How much current through your headphones/ear
pieces do you need to hear the signal you want? (This is assuming you
are not amplifying the signal, which if that's the case, what's the
point in building a xtal set?).

What is the impedance of your headphones/ear pieces? They will
dictate the "loaded Q" of your tank circuit.

The simple correlation between risetime and bandwidth is roughly:
BW = 1/(3ï¿½t)

Unfortunately, peaking bandwidth can degrade risetime, and vice-versa.
O'scopes have a lot of conflicting adjustments within them. The
TEK545 had something like an 8 to 12 hour tune-up procedure for the
average bench tech (a calibration specialist could do it in 3 to 4
hours).

Hi Richard,
It all affects the loaded Q, the antenna, the diode, the audio matching
transformer and headphones.
I think the ideal is to impart maximum power to the tank circuit from the
antenna, now you have an
AC power supply with a known source impedance. Then pick your diode and
transformer match
your headphone for max power out...
I'm going through a mental exercise to build the most sensitive crystal
radio I can.
The best scenario would be to build a headphone with about a megaohm of
impedance
and eliminate the matching transformer losses. Here's one form that could
be modified.
http://www.hpfriedrichs.com/images-votc/gallows.jpg
If it's not self explanatory, you connect a stethoscope type headphone to
the tube that sticks out.
So to rephrase my question, how do I raise the impedance of an antenna to a

very high impedance
with minimum losses?

Not what I would call a megOhm Z candidate in any form as this is the
model for the commonplace 600 Ohm (telephone standard) to 1KOhm
headphone of antiquity. It uses a coil. You should be looking at
piezo.

> So to rephrase my question, how do I raise the impedance of an antenna to a
>very high impedance
>with minimum losses?
> MikeK

You could shorten the antenna to an inch or two for AM, but then it
would be shorter than your tank coil, and hence your tank coil should
be the antenna.

This was a toy commonly found in the late 50s when I got it for
Christmas. It was shaped like a Buck Rogers space ship with a ball
handled plunger as the nose cone that adjusted the ferrite in the core
of the coil (to be used as a tuner). Of course the longest wire was
the earphone lead (all of a foot or 18 inches which would still
constitute an extremenly high Z antenna that you seek).

I lived outside of San Francisco at the time, and AM stations were
unknown to it. However, I could get some Marine traffic like the
Coast Guard (I had a view of the Ocean from the hills around Pacific
Manor, now Pacifica).

Very uninspired performance to say the least.

Hello Mike,

Assuming you have a long wire outside and a ground provision, you may use an inductive coupling. By changing the distance between the antenna coil and the receiver coil, you modify the impedance transformation.

Other method is capacitive coupling. Probably positioning the end of the antenna wire close to the high impedance side of the tank circuit will give the desired effect. Changing the distance changes the coupling.

For inductive coupling, your receiver circuit can be floating, for capacitive coupling, the receiver should be grounded.

By changing the coupling you can optimize for maximum selectivity (with reduced sensitivity) or maximum sensitivity (with reduces selectivity).

Regarding the antenna, assuming LW and AM reception, long combined with high gives strongest signal, hence you can reduce the coupling to get best selectivity.

Best regards,

Wim

Piezo is a candidate, but also on the table is a C shape laminated core
with a
small gap. The gap will be large enough that a small magnet will fit in it.
The magnet
is connected to a lever and on the other end is a diaphragm. The core will
be large
enough to hold thousands of turns. Possibly even a E I core with the a gap
milled in
the center leg for the magnet/lever assembly. A coil can be put on each of
the outer
legs. Not sure, but I think the center leg should be cone shaped to focus
the magnetic
field at the magnet. The magnet/lever assembly should have low mass.The
coils will
have taps for a va
Anyway that is the idea I'm working with at the moment.
Regarding piezos, I envision multiple piezo with a switching arrangement to
alter the impedance to match the impedance of the radio.

It seem a common method to couple the antenna is just a single series
variable capacitor. I don't know if this method couples maximum energy to
the radio. ??
Normally we transform our antenna to 50 ohms, in this case we would like
to see 1 million ohms, I'm not sure that can be done, and if it can the
losses
may be higher than having a mismatch.
Thanks, MikeK

Those distributed inverters are becoming more popular, because they solve a lot of problems.
a) you can size them to be some small number of panels worth, where the sweet spot is for component costs internally. Many smaller inverters can be cheaper to make than one big inverter, once you get beyond, say, where a single semiconductor device is big enough. (like solid state power amps for RF)

b) you don't have to worry about high power DC wiring, which is a real pain for things like fusing and grounding.

c) you've already got to have the line synchronization figured out, and it's done in a single ASIC anyway, so there's no added complexity for paralleling and scaling. Just rack and stack

It might also help with the firefighter problem.. they aren't wild about big solar installations because there's no easy way to turn them off. cut the wires and they're still live, as long as light is shining on them. I haven't looked in detail, but I could see distributed inverters each having their own "disconnect" switch to short the panel out, and if you drop the master interconnect (so there's no grid-tie), then all the panels will isolate themselves by design, and all the AC wiring will be dead(-ish)

This doesn't sound like a Crystal radio project at all. You describe nothing that comes close to even 1KOhm, much less 1MOhm in load. Your descriptions all use appeals to sensitivity, not impedance.

> Trying to maximum signal for contest situations want a longer antenna.

This confounds your desire for higher Z. In the extreme (antenna of several wavelengths and necessarily close to ground) will be less than 1KOhm. In the mid-range, could be hi-Z IFF it is a halfwave long. In the conventional lengths, some may pose a moderately hi-Z (maybe KOhms). None will exhibit the Z you anticipate for your Tank.

As I said, start thinking backwards from the power delivered to your ear. Can you express that as a number? Not much point in the rest of this if you cannot.

Richard you are right, I read it wrong.
I thought he was just being smart because it's a crystal radio and he wanted
me
to just grab a alligator clip and connect the antenna (I missed the taps
part)
I apologize J.Todd.
Connecting the antenna to taps on the coil is common, I don't believe this
method transfers maximum energy into the tank circuit, But I am open to more
info about that.
Also I expect any high performance crystal radio to be made with
litz wire, I suppose taps could be made to litz but I have looked at a lot
of
radios and don't recall ever seeing taps on a litz wire coil.
J.Todd I apologize for my smart alec remark.

Yes, with the correct value, it will.

Hello Mike,

Regarding the 1M Ohm impedance.
If you can make a tank circuit with 1MOhm impedance at resonance, you

can transform your antenna impedance to that value. You use your resonant circuit as part of the impedance transformer. Even in case of a ohmic 50 Ohms antenna impedance, you can transform this to 1 Mohm (inductive or capacitive coupling). Maybe you have to combine the coupling capacitor with a tap on the coil.

Regarding your detector.
In the detector circuit you transform a high impedance (around 1 MOhm) to a lower impedance to find the sweet spot for your detector diode / LF load combination.

If you have a simulator (for example SPICE type SW), you can model your antenna as a voltage source in series with a capacitance (pF range) and some resistance (1..100 Ohm range, depending on ground provision).

By changing the coupling capacitance from the antenna to the top of your resonant circuit, you can see what happens (in an .AC sweep). You will see impedance transformation (that is more output voltage than input voltage) and of course some detuning of your circuit because of the additional capacitance.

If you want to do some hand calculation, search for: L impedance transformation network.

Best regards,

Wim

Hi Richard,
I have probably confused things, I have 4 or 5 threads running at this
time.

The C core EI core thing is a starting attempt to build a speaker with a
high impedance
to eliminate the losses of a matching transformer. The whole excercise is to
build a crystal
radio that will eack out the most sensitivity.

1 picowatt to the earphone is a good number.

For sensitivity the starting point has got to be the tank circuit, you
want to build
an inductor with very high Q and then mate that to a good quality capacitor.

A Q of 1000 is possible over much of the AM BCB.
Can we agree on that?

Now you need to couple in energy from an antenna. If this is adjusted for maximum power transfer, we have reduced the Q by 1/2 or Q=500.
Assuming a 240uh inductor and frequency of 1 Mhz the XL is 1507 ohms, multiply that by the antenna loaded tank Q of 500 and we have an Rp = 753,500 ohms.
Does that work for you?

I think I found a good site for the antenna matching;
http://www.crystal-radio.eu/enantunittest1.htm

Now we need to detect and tranfer the signal to a transducer

I'll stop here till I get some feedback, I don't know my question anymore? \ :-)
Mike.

> you drop the master interconnect (so there's no grid-tie), then all the
> panels will isolate themselves by design, and all the AC wiring will be
> dead(-ish)

there is also no big battery to be serviced or replaced, or to react
with heat or water.. another plus for firefighters. in this
installation there is a breaker box for the 4 rows of panels on the
pole at the panels, a meter box on the end of the house near the
panels, and another breaker where they tie into the main panel... any
one of them is enough to kill power from the panels... and they also
shut off automatically when the grid goes down to prevent backfeeding.

Well, you have to move beyond "believing" and do some analysis.

Broadly, adjusting the tap point, and retuning for maximum output is finding the point of maximum power transfer for the given components and source impedance.

I am quite skeptical (that is like "don't belive") that your scheme for headphones is going to deliver what you suggest.

When I was a kid, these things here ALL used a crystal (or piezo) earpiece, which has an impedance that looks like extreme R and a very small shunt C, in all a very high impedance at audio frequencies of interest.

Look at http://www.jaycar.com.au/productView.asp?ID=AS3305
&keywords=earpiece&form=KEYWORD for an example. (You probably will need to fix the split URL. They also have a simple crystal radio kit in the catalogue, no doubt suppliers in your country do also.

Traditionally, these were used with improvised smallish antennas, eg bed iron, and that brought in too many stations. To obtain benefit from enhanced sensitivity, you might need to be in a very quiet location, and have extreme selectivity... both are practical issues.

You may want to make sure this enough to be audible. An iPod may output 30 milliwatts which is probably more than you would ever need/get. 1 picowatt to a headphone may not be sufficient.

Won't both the antenna and the load serve to reduce the Q? You need to be looking at how power is transferred from the antenna to the earphone. Trying to optimize one part at a time may not yield the best result.

Hey Owen,
Ok, so we find a tap that is the match to the antenna and then maximum
energy is
transferred across the turns from the tap to ground. And because those turns
are tightly coupled to the rest of the inductor the maximum energy is
transferred from
the antenna to the inductor.

The speaker build was a different thread but I'll pass along what started
me thinking.
http://www.hpfriedrichs.com/images-opp/gordon-mccall/gallows1.jpg
and
http://www.hpfriedrichs.com/images-opp/tom-kipgen/toms-ear.jpg
These are speakers that drive a stethoscope style headphone.
So I was thinking with a larger core so I could wind a high impedance
electromagnet and with new high flux magnets have something more sensitive
than conventional headphones.
Here's a concept drawing;
http://i395.photobucket.com/albums/pp37/Qmavam/Sensitivespeakershapedpoles.jpg

I can only go by what I have read on the crystal radio groups and they
say 1pw
is audable with very sensitive headphones..

Ya, it would limit bandwidth. But to much Q is easy to solve and hard to
get.
That is only unloaded Q of the tank, adding the antenna brings that down to
Q=500.
Then comes the load from the detector and then the audio transducer
assembly.

Yes, absolutely. I think the optimization is in the tank circuit after
that
it is impedance matching.

Hi Mike,

You should consider their being very good at this then. 1 pW is the lowest limit of hearing at 1KHz. No speaker/transducer is 100% efficient. So, automatically, this claim you have read is suspect in the highest degree.

Let's work these numbers further. The transducer elements you have been describing may be sensitive, but that is not the same thing as efficient. Given that they are ancient magnet and diaphram constructions, they would be pushing the limits at 10%.

Further, your chosen power level of 1pW would not be heard but in a very special anechoic chamber, and even then your heart and your breath would be in competition as QRN. Speach as perceived to be at normal quiet talking levels would be 40dB more powerful (and, again, in a quiet surrounding like a library). This would be a normal expectation of program content sound level.

Being generous (good efficiency and whispers at 1 meter in the library), I would suspect that your receive power level would be closer to 1nW and this would be straining things for a real listening experience.

In the middle of the band, it would give you poor telephone audio
quality. However, many hams find it suitable for DX work.

Good enough to pitch back and forth, much as your power level.

See the following article:
http://www.eetimes.com/design/microwave-rf-design/4018867/Choosing-an-Oscilloscope-with-the-Right-Bandwidth

There are two paragraphs in the article of importance here:

"All oscilloscopes exhibit a low-pass frequency response that
rolls-off at higher frequencies, as shown in Figure 1. Most scopes with
bandwidth specifications of 1GHz and below typically have what is called
a Gaussian response, which exhibits a slow roll-off characteristic
beginning at approximately one-third the -3dB frequency. Oscilloscopes
with bandwidth specifications greater than 1GHz typically have a
maximally-flat frequency response, as shown in Figure 2. This type of
response usually exhibits a flatter in-band response with a sharper
roll-off characteristic near the -3dB frequency.

"Closely related to an oscilloscope's bandwidth specification is its
rise time specification. Scopes with a Gaussian-type response will have
an approximate rise time of 0.35/f(sub)BW based on a 10- to 90-percent
criterion. Scopes with a maximally-flat response typically have rise time
specifications in the range of 0.4/f(sub)BW depending on the sharpness of
the frequency roll-off characteristic. But it is important to remember
that a scope's rise time is not the fastest edge speed that the
oscilloscope can accurately measure. It is the fastest edge speed the
scope can possibly produce if the input signal has a theoretical
infinitely fast rise time (0 ps). Although this theoretical specification
is impossible to test (since pulse generators don't have infinitely fast
edges) from a practical perspective, you can test your oscilloscope's
rise time by inputting a pulse that has edge speeds that are 3 to 5 times
faster than the scope's rise time specification."

My experience with mobile vertical whips has been similar, I guess at least
in my case the location of the antenna was always a compromise and car
body's are not designed to be ideal ground plans.
I did get quite good at knowing where some of the good lobes were and
positioning the car accordingly.

Hi Mike,

Where did the search for hi-Z go when this 16Ohm speaker was hauled out for listening? OK, sure, it is all a matter of making a match - I can go with that.

Let's do the math and see where that leads us for the specification offered:
SPL @ 1W/1m: 112.5dB

When driven by .0078 pw we find ourselves 140dB below the 1 Watt that yields 112.5 dB SPL heard at 1 meter. That translates to -27.5dB re the absolute lowest level of hearing.

OK, supposing you are not 1 meter away from that speaker? I can well anticipate that you would expect the stethoscope lead comes in to rescue this claim. Does it get us to within 1mM of the cone to make up the difference? Your ear can not get that close (maybe a cM) and the volume of air in the tube makes it worse (unless we are using an Hemholz resonator, and at that, the program material goes out the window).

Being generous and saying the claim is off by 1 decimal place still has us sitting in an anechoic chamber. No one has that kind of bucks for a hobby pursuit except Bill Gates. Even then, this is about the threshold of hearing for a juvenile. Is your scribbler 17 years old? I can well imagine you, like myself, even that age out - 3 to 4 times over. Program content is going to depress these readings by roughly 5dB for age and another 5 to 10dB for frequency variation.

If you want to copy 1WPM CW at 1KHz, this may fly (if you are buried alone in a cave in South America). Who transmits A3 modulated CW (yes, a contradiction in acronyms where CW commonly means morse code) these days?

So, on the commonsense side of this, no that myth is busted.

The author explores efficiency and states:
>The efficiency is 7.03ï¿½W / 56.8ï¿½W = 0.123
Which was my generous offering in an earlier posting (however, the author stipulates this is a total conversion efficiency for both

speakers).

Going further we observe:
>The efficiency is quite varying with different frequencies, at 1 kHz there was a peak.
>At other frequencies the efficiency is lower.
>This can be caused by resonances in the speakers, because this situation with two speakers connected is quite different from the normal use.
Normal use indeed (what I call listening to program content). There is every chance that the coupled speakers were driven at a hemholz resonance. Using the scope probe as a crude ruler, the volume of air looks to be close to a half wave long.

Note the leading stipulation again:
>The efficiency is quite varying with different frequencies
... indeed.

I have had a hearing test in specially designed chambers, employing a test that eliminates guessing when the sound is, or is not there. I've even designed testing systems that use that methodology for measuring Army helicopter pilot alertness. The psychological pressure of expecting to hear a faint sound can drive results that are impossible to replicate without that testing protocol.

Think you could follow the chain of reasoning here to cross-check the other transducers' performance? If it is on par, then you can trust the testing methodology. If my back-of-the-napkin calculations are off, this will reveal it.

Give me a break will ya?
You had said, "As I said, start thinking backwards from the
power delivered to your ear. Can you express that as a number? "
I inserted 1pw.
You then said "this claim you have read is suspect in the highest degree."
So then I find a reference that says .0078pw which is even 12db less than
the claim that is "suspect in the highest degree"
That's how I brought up a 16 ohm speaker.
Richard I'm not disagreeing with you, I'm learning here, I don't have the
knowledge or the math skills to do that. I end up looking up sources, such
as minimum hearing threshold and going to online converters to try and
follow your descriptions, which I appreciate. :-)

I'm exploring other ways that could eliminate
losses. The transformer he would use to transform the 16 ohm speaker
to 1.62 Mohm has about 1.5 db of loss. If I had a 1.62 Mohm speaker
with eqivalent sensitivity to his 16 ohm speaker, I would have a
1.5db gain. Not major but helpful in the search to cut lossses.

Hmm... seems to match what I found for minimum hearing threshold.

I don't know but I suspect he just held the Adastra driver up to his ear
for his tests.

Ya I'm on the upper end on SPL needed for perception.

Hi Richard.
Near the bottom of this page http://www.crystal-radio.eu/entrafounit1.htm
The author relates this about the use of his 1.62 Mohm input impedance
transformer driving the Adastra 16 ohm driver.

"when I connect a driver unit to the output of the transformer unit, a
1 kHz test tone on the transformer unit input with a amplitude of
1 mV peak-peak can be easily heard."

So, 1 mv peak to peak is .0003535V rms. V^2/R so .3535^2/ 1.62Mohm =7.7 x
10^-14
Or 0.077pw.
Hmm... that is a factor of 1 decimal unit from his earlier claim.
Or did I make the mistake???
Could this measurement have been made with a x10 scope probe and not noted
in recording of the measurement?
That would increase the power to 0.77pw, getting very close to the minimum
threshold
of hearing.
Inquiring minds want to know.

Hi Mike,

As you have allowed, error can wriggle into any part of the
computational chain and slip us a 10dB hit, or a 10dB bonus.

I've calibrated laboratory grade Brï¿½el & Kjï¿½r microphones and the
process is not done in one sitting.

Here is a very good, online calculator that you should play with:
http://www.ajdesigner.com/phpsound/sound_wave_equation_spl_sound_pressure_level.php
I asked you for a base power, there is also the matter of distance
from that power source to the ear drum, also the volume of air
involved. By using a combination of these offered equations, you can
(with scrupulous note-taking) find out all the cogent details.

I won't go into the matter of the perception of sound, and the
variation in that with the difference in transverse or longitudinal
sound pressure waves. However, as the word perception is now
introduced; when human senses enter the world of measurement,
measurement becomes vastly more complex (simply because we can fool
ourselves into believing anything). Eliminating the observational
bias is an enormous task.

A simple observation flows from that. Take those two speakers, face-to-face. I mentioned they constructed a tuned hemholz resonator. Connect your ear tube to that column. The Q of that resonator is going to take any ambient noise, select out the resonant frequency and amplify it. Guess what? You get to hear a signal that was never applied to the leads! Belief can make for a tenacious trap.

Returning to J. Todd's post:
>Put an alligator clip on the antenna lead and run it down the tank to
>find max volume, then clip it on.
Gives you absolutely EVERYTHING you need. And, frankly, I am surprised about your source material bemoaning the transformation loss of using a transformer to connect their speaker to the Tank.

Consider that the Tank is, as it suggests, the repository of all the power available to you (a "gas tank" as it were). That same Tank is ALSO a universal matching unit. Along the length of the coil (let's pretend that you can connect alligator clips to any point along the length of that wire) you have a new Z transform of the entire circuit. Basically from extreme hi-Z to extreme lo-Z and all Zs in between. The detector/filter/speaker goes to the point that best matches (pun intended) its Z (or some dozen or two dozen Ohms) and the antenna goes to its own value Z (some thousands of Ohms) along the length of the coil. You already have a transformer, what is the need of a lossy, second unit?

Of course, these connections are going to perturb the Tank and move it from its rest point. So is any other form of connection. The trick is to accept this and design that into the final product.

If you have time could you verify the 1 decimal point error that
his own numbers show. It is in the 4th to the last line on this page.
Near the bottom of this page http://www.crystal-radio.eu/entrafounit1.htm
I have contacted him once for clearification of steps on one of his pages.
He has remove his email from some pages and says he can't answer email, he
also
closed his online store.
I don't want to contact him again unless I'm sure that a correction should
be made.

Regarding 10db errors, I have physicist friend that worked for sonics
company,
he found their reference equipment in the water tank had a +10db error.

He reported that to his superior by showing that a transducer he designed had more
output than the input.
The superior was very happy the design, the superior didn't get the jist of what my
friend was trying to show him.

Perception may have been a bad word to introduce but even if you call it threshold of hearing you still have the same problems you point out.

Placebo,
Can you say Power Balance Bracelet, homeopathic medicine, magnetic shoe inserts or the best one Magic Female Relaxant Fragrance also called "The Relationship Extender" because it can help you to settle differences, and allow you to happily co-exist with a woman even at the most difficult of times. :-)

First,
I'll rephrase what I think you meant to say, I am surprised about YOU bemoaning the source material transformation loss of using a transformer to connect their speaker to the Tank.
Even I worded that poorly, but are you suggesting I should not work for 1.5db?

Second,
Tapping down on the tank coil may not work as well as first thought.
You still have diode characteristics to overcome, and as you tap down the voltage
also decreases. I throw this out not fully aware of how lower voltage, lower impedance affects the diode characterists, but I know the characteristics will
change with current. I"ll add the contest guru's that I have noted use high impedance taps to the detector. Although depending on signal strength they switch in diodes that better match the current the radio signal is delivering.

Still hyave concern about diode characteristics.

Thanks, MikeK

Why start with a 1.5dB deficit when the Tank is already there to do
the work of matching at no loss?

> Second,

You are going to have to explain that better, because what follows
doesn't.

Changed voltage / changed current = changed Z

That's why the Tank is also called a transformer. You could displace
that function into a secondary, lossy transformer, but the same thing
will happen insofar as your last complaint. In other words, you can
add more loss and get the same grief.

>I"ll add the contest guru's that I have noted use high

Do they offer a case for fumbling through a selection of diodes? At
first blush, the best is going to be the best - hands down.

You have the diode to drive before the audio section and you want to match
the
diodes impedance. Tapping down will allow you to match diode impedance, but
I'm not sure tapped down is where you will find the best diode efficiency.
Your response to my "not sure " is anticipated. :-)

>
> You are going to have to explain that better, because what follows
> doesn't.

>>You still have diode characteristics to overcome, and as you tap down the
>>voltage also decreases.

"Here's a quote from Ben Tongue's webpage;
Many times the question is asked, "What is the best diode to use?" The
answer depends on the specific RF source resistance and audio load impedance
of the Crystal Set in question. At low signal levels the RF input
resistance and audio output resistance of a detector diode are equal to
25,700,000*n/Is Ohms (current in nA). For minimum detector power loss at
very low signal levels with a particular diode, all one has to do is
impedance match the RF source resistance to the diode and impedance match
the diodes' audio output resistance to the headphones by using an
appropriate audio transformer. The lower the Is of the diode, the higher
will be the weak signal sensitivity (volume) from the Crystal Set, provided
it is properly impedance matched to it's circuit (see article #1). This

does not affect strong signal volume. There is one caveat to this, however. It is assumed that the RF tuned circuits and audio transformer losses don't change. This can be hard to accomplish. It is assumed that the Rs, diode junction capacitance, n and reverse leakage are reasonable. If the diode you want to use has a higher Is than the optimum value, tap it down on the tuned circuit. If the diode you want to use has a lower Is than the optimum value, change the tank circuit to one with a higher L and lower C so that the antenna impedance can be transformed to a higher value and repeat step #1. "

And yes I note the "tap it down" which is used to match the impedance of the diode.

See above.
And yes they sometimes multiple diodes on there radio.

>> Still hyave concern about diode characteristics.
>

Saturation current and
axis-crossing resistance equal to Rr
Sorry that's two, but their related.

Well, all of that sounds good until I went to Tractor supply and
couldn't find what you were talking about.

I did find this:SKU Number: 3610032 but they are only 4 inches long.
They talk of its staples, too.

Can you tell me the store and product numter that you are talking
about?

Thanks

Joe

Hi Mike,

Unfortunately your response is not an answer. Your response suffers
equally for the proposed additional transformer - and you have added
loss for no net forward movement to the solution.

Frankly, it looks like spaghetti math. If it suits you, then there is
a number that will supply the optimal solution - that is the nature of
math, after all. However, too much of this looks circular, especially
when I see complexity piled on top of loss just to return to the same
problem.

However, what it all boils down to is that you have to live with
whatever diode you select, and you shift the tap for the best
performance (not many variables left in the game of Xtal radios, is
there?).

Hi Mike,

This seems to wander the field when there are conflicting agendas on the table. The wandering is due in large part to the absence of specific numbers, and in this particular case, even the sense of scale.

We have an audio Z match. We have a diode Z match. There is no sense that if this is a high-Z or a low-Z for either/both/neither.

To this point, you have hewed to the commonplace magnetic speaker, and from that I can only imagine that the problem with audio match is transforming from a high (diode) Z to a low (speaker) Z. But from the numbers, it would seem that both diode and speaker Zs are on par. I could be wrong because this drift takes me into guessing.

Solve your problem and get a piezo headphone (or make one, this is the tradition of Xtal radio, n'est pas?). They have to exhibit at least 10KOhm if not a bajillion ohms. If there isn't enough current to fire the diode, Guess What? Slap a sacrificial resistor across the piezo leads!

Radio Shack sells (or used to the last time I bought one) two or three inch barium titanate ceramic disks that are offered as buzzer elements (or rob a clock alarm for its buzzer - these things are a drug on the market).

* * * * * * * * * * *

Now, if you only return to complain that the Hi-Z phones cause a problem somewhere else; then I would recommend you abandon circuit design and take up the study of math employing figures of merit. Such assignments of merit are subjective, of course, but then you get to own your personal solution. Discussion that follows this satisfactory conclusion then enters the appropriate arena of philosophical or religious controversy. This will certainly garner far more participation in this group.

Every time you change frequency you change source resistance.
XL times Q equals source resistance, Q changes with frequency,

and XL changes with frequency.
Also when you change to a different station with a different signal strength
you change the current through the diode, this changes the resistance the
diode
presents to the tank.

There are dozens of diodes to pick from, depends on the tank Z
and signal strength. I don't know what you mean when you say there aren't
many variables, there are many, many!
Coil Type (solenoid, spider, 3D solenoid)
Coil Form Material, paper, PVC, polypropylene, etc.
Wire type, solid, Litz
Antenna Match technique, Tap, cap tune, inductance coupling
Diodes, Diodes, Diodes
Audio, Transformer matching , high impedance piezo, sound powered
headphones, crystal earphone, horn driver.

Here's some more info on the diode selection and why.
Richard I'm well aware of your great knowledge (not being facetious)
and my lack of math and knowledge on this, but I'm to the point where
it seems you are not willing to learn new information. It seems you already
know it all. This especially in regards to the idea that the diodes
characterists
are very important to losses in the radio.
I think one of these pages has a graph showing a diode not matched to the
current available has a 33db loss.
Here's more diode info.
http://www.crystal-radio.eu/endiodes.htm
http://www.bentongue.com/xtalset/17Is_n/17Is_n.html
http://www.klimaco.com/HAMRADIOPAGES/xtal_how_to.htm

I do appreciate your time and the discusion, I did learn from it.
I'm going to take a few days off.
Sincerely, MikeK

Richard-

We have a diode detector, which is nonlinear. If you allow a filter capacitor on its output, there is current flow only on alternate RF voltage peaks, in order to charge up the capacitor for the amount lost to the audio load during the cycle. Its effect on circuit Q may be a fraction of the total, also consisting of coil Q and input circuit matching.

Therefore you want the diode connected to the high end of the coil, not transformed to a lower impedance point on the coil.

Load impedance will affect audio level, so should be kept high for that reason. However there may be some value of load that produces the greatest audio output voltage. If too high, the filter capacitor would charge to the peak of the modulation waveform and stay there.

Worst case is a low impedance audio load and no filter capacitor. Half of the RF waveform is essentially cut off, leaving a peak-to-peak value of one half the open circuit value. Since energy is extracted from the circuit during the conduction cycle, the effect on Q should be approximately the same as if a resistor having the same peak-to-peak effect was connected across the circuit, disregarding the RMS value of a half-sine waveform.

Hi Mike,

There are a number of problems here. Q is strictly a function of
RESISTANCE and nothing else.

What you call source resistance, when using the math you provide, is
actually source impedance. Impedance embraces resistance and is
solely resistance when reactance is gone - such as at resonance.
However, it would seem that the Xtal Radio community treats reactance
as resistance interchangeably.

That is fine to a point, but it introduces serious problems in the
usage of the term "match" as there are actually several types of
"matching" and each has its peculiarity (only peculiar when you are
unfamiliar with the other types).

It is a given that you are going to have to change either Xc or Xl if
you are going to tune to another frequency. This alters the circuit
Z, certainly; and for the AM band you have a 3:1 variation from band
end-to-end.

>Also when you change to a different station with a different signal strength
>you change the current through the diode, this changes the resistance the
>diode
>presents to the tank.

Without numbers, this is like anticipating worry about your MPG
driving up a hill in comparison to driving down the same hill. Yes, a
wild variation, but do you give up cars and start walking instead?
Some of these "concerns" sound like they come from the AVC needy. I
thought Xtal Radio folks would man up and get with the program.

>> However, what it all boils down to is that you have to live with
>> whatever diode you select, and you shift the tap for the best
>> performance (not many variables left in the game of Xtal radios, is
>> there?).
>

>There are dozens of diodes to pick from, depends on the tank Z
>and signal strength.

No, actually you've either mis-read the intent (which is certainly a problem with that author's hodge-podge writing style) or you've read too many written sources that each only see part of the elephant.
"It's a snake! We need something bulky."
"It's a wall! We need something slim."
"It's thin and flappy! We need something sturdy."

The problem with the diode is in its forward current and reverse current. If they are about the same, you don't have a rectifier. This would be a weak signal problem. The forward current defines the series resistance of the diode and how much that is in comparison to the load defines the efficiency. You want more current to lower the diode resistance to increase the efficiency. Unfortunately this demands you have a higher source voltage that offers less current (Catch-22).

However, this problem is strictly for a low Z load like a magnetic speaker - and thus enters the consternation over competing agendas that gives everyone the fits that seems they enjoy agonizing over when the solution is obvious. I will touch on that next:

> I don't know what you mean when you say there aren't
>many variables, there are many, many!
>Coil Type (solenoid, spider, 3D solenoid)
>Coil Form Material, paper, PVC, polypropylene, etc.

Those are non-starters for those who love to struggle in hope against reality.

>Wire type, solid, Litz

Ah yes, the magic Litz wire that is the salvation. The solution for the problem that doesn't matter. You do this because you can, not because you need to. And then you return to life with the car still in the ditch (but you changed the air in the tires).

>Antenna Match technique, Tap, cap tune, inductance coupling

This has been long figured out. For nearly a century.

>Diodes, Diodes, Diodes

Whose solution is found in:

>Audio, Transformer matching , high impedance piezo, sound powered
>headphones, crystal earphone, horn driver.

Whose choice is obvious in hi impedance.

Like I said, there are not that many variables, until you find someone on a soap box with a stump speech about the invidious dereliction of design introduced with the Philips head screw. The advantages of the

Bristol head anyone?

Do not confuse the multitude of competing and contradicting factors as
the multitude of variables.

Introduce figure of merit to the discussion and argue about that. If
that gets resolved, the solution will pop right out.

> Here's some more info on the diode selection and why.
>Richard I'm well aware of your great knowledge (not being facetious)
>and my lack of math and knowledge on this, but I'm to the point where
>it seems you are not willing to learn new information.

There is no new information. It is a niche application you are
talking about, not new science. The niche has its concerns and they
are impacted by issues that are rarely a problem for the standard
usage of the components you mention, but there have been no new
devices introduced in this discussion. I see nothing innovative. In
fact, the discussion is so in-bred it lacks coverage outside of a
clubbish mainstream. I will offer something new below that is
actually quite old.

>It seems you already
>know it all. This especially in regards to the idea that the diodes
>characterists
>are very important to losses in the radio.

I have designed at the extreme edges of component characteristics,
true. More often in regard to temperature variation, mechanical
vibration, noise, accuracy, resolution, speed, bandwidth, linearity -
all that went towards continuous service in a largish orange box in
some jets.

I have studied diodes to no end, especially LEDs and photodetectors.
Talk about marginal signal detection and loss. I started with 1n34s
being used as varactors back in the late 60s. PIN and Tunnel diodes
followed. There is a world of non-linear devices out there. I
especially like the surgistor and posistor. Any reports of their use
in Xtal sets?

I have maintained a number of audio standards and measurement devices.
I have had to repair detectors that measured absolute value voltage
out to 7 places, the same issues arose there too. Small currents?
Like those that rise continuously through the air in femto-ampere
levels? You would need polonium treated probes to measure them (or
just use the anti-static record brushes of the 1970s).

> I think one of these pages has a graph showing a diode not matched to the
>current available has a 33db loss.
> Here's more diode info.
>http://www.crystal-radio.eu/endiodes.htm
>http://www.bentongue.com/xtalset/17Is_n/17Is_n.html
>http://www.klimaco.com/HAMRADIOPAGES/xtal_how_to.htm

This stuff merely shows the agony of counter trending data. In other words select the optimal Is and you get trash Rd - and vice versa. Reporting the numbers doesn't solve the problem however.

* * * * * * * *

In this offered discussion there is nothing of how the pioneers managed it with galena crystals and cat whiskers. That data for comparison is starkly absent in this and their discussion.

My Fourth Edition of "Standard Handbook for Electrical Engineers" (1915) offers Coherers and Magnetic detectors. The coverage is likewise absent of these alternatives.

"Section 21-289 Contact Rectifiers. The rectifiers most frequently consist of a contact between a fine wire and some variety of mineral. Among the minerals frequently use are iron pyrites, galena, silicon, and molybdenite. In other forms, two crystals are used in contact, such as zinkite with chaleopyryte or bornite, or silicon with metallic arsenic.
"For detecting the direct-current pulses, head telephones of from 1,000 to 3,000 Ohms resistance are ordinarily used."

Returning to the obscure references, for magnetic detectors, consider:
http://en.wikipedia.org/wiki/Magnetic_detector
for the coherer, consider
http://en.wikipedia.org/wiki/Coherer

* * * * * * *

You might want to reflect that this thread has not been about matching an antenna to a crystal radio at all. That topic was rather easily and quickly answered by J. Todd. Loss is defined by wire resistance and the proximity of objects to the tank.

The match from the Tank is similarly simple - once you define the load. Loss is defined by wire resistance and the proximity of objects to the tank.

The load is presented as its two native components: the detector and the headset.

The detector is the variable of concern, it is defined by the current necessary to drive the headset, everything surrounding the detector has to conform to its choice. The loss is defined by the ratio of the detector resistance to the load resistance plus that diode resistance.

The headset is defined by a power level you identified as one picowatt delivered to the ear. I think we can agree that was very generous. The loss is defined by the transducer efficiency.

This is the genesis of figure of merit, and that is your solution.

> 25 million WHAT?
>
Ok One more, with a little help I figured it out.
It has to to with the Thermal Voltage of the diode.
Vt=KT/q
with k=1.38E-23 and q=1.6E-19. T is absolute temperature in degrees Kelvin,
k is Boltzmann's constant and q is the charge of an electron. VT is close
to 0.025 volts at 20 degrees Celsius.

With a slightly increased temperature the .025 is raised to .0257,
and .0257 / 1 nanoamp =25,700,000
Thanks, MikeK

Hi Fred,

The subtext of that observation was the lack of numbers.
Quantification will aid immensely and give perspective to the direness
of the problem.

>We have a diode detector, which is nonlinear. If you allow a filter
>capacitor on its output, there is current flow only on alternate RF
>voltage peaks, in order to charge up the capacitor for the amount lost
>to the audio load during the cycle. Its effect on circuit Q may be a
>fraction of the total, also consisting of coil Q and input circuit
>matching.

This is dangerously close to decoupling the problem by looking at
minutia. Q is the ratio of power in to power consumed.

>Therefore you want the diode connected to the high end of the coil, not
>transformed to a lower impedance point on the coil.

Your detector placement serves the consumption side and consumption -
listening to program content - is the whole point of detection.

Preserving Q does not serve that goal.

>Load impedance will affect audio level, so should be kept high for that
>reason.

Audio level "should" follow power applied, be it low voltage high
current (a speaker); or high voltage low current (a piezo). Preserving
power levels while changing its form is the purpose transduction.

>However there may be some value of load that produces the
>greatest audio output voltage. If too high, the filter capacitor would
>charge to the peak of the modulation waveform and stay there.

What you describe is a clamp, not a filter; but point is well taken.
What you have is the wrong balance of charge time to discharge time.
In other words, you have selected the wrong detector for the chosen
transducer, or vice-versa. Choose both to complement each other.

Consider, what would be lost if you clipped out that pesky cap?

Ya, loss resistance of the tank.
Can you agree that it varies with frequency?

The tank is used at resonance, so yes, source resistance.

> I will work, just not well.
> MikeK

True, but operating crystal radios is much like sailing.

Maybe multiple taps is not that bad an idea.

- I never saw a crystal radio optimized for such a small tuning ration that the LC had a fixed impedance. A 1-to-3 tuning ratio is quite normal, and tank impedance will therefore vary considerably.

- On medium wave the impedance of the electrically very short wire antenna will vary, but not that much. It will stay probably in the order of a kiloohm or more. On shortwave it will swing considerably.

- If the receiver has to resolve different stations or at least clearly separate different SW broadcast bands (to listen to the most powerful broadcaster in each band, more is not doable), it may make sense to reduce the loading below optimum energy transfer at the resonant frequency.

This suggests that a coil with multiple taps could be useful. If the radio has a tapped coil and 3 croc clips (one each for the tuning cap, antenna, and detector) the user has to optimize over 3 dimensions in, and 2 dimensions out - wanted signal level and interference.

Great fun, but not easy.

The human ear is not linear and tends to be a bad level measuring instrument. It helps if the radio also has a microamp-meter to make relative linear comparisons in total signal level. A 50uA meter may have a DC resistance of 2kohm and load about the same as a magnetic headset, but a 500uA may be sensitive enough and load less.

The combination of separate improvements that the ear alone could not judge may in the end be considerable.

A digital voltmeter would be so high impedance as to be practically invisible even at very high impedances too, but it has a battery powered DC amplifier. IMO it is aesthetically incongruent with a RF-powered radio.

I like your very practical advice here, Wim. For Mike, as Wim noted
in another post, you can simulate this in Spice quite easily. While
you're playing with it in Spice, you might also look at two high-Q
tanks, tuned to the same frequency, with a non-zero coupling

coefficient between the inductors. Excite the first with a voltage generator in series with the RLC tank, or a current source across it, and observe the frequency response at the second tank. Vary the coefficient of coupling between the coils and notice how small it is to get critical coupling. If you use LTSpice, you can use a .step statement to run a set of simulations over a range of k values, for example.

The flip side of this is that in LC filters that are very narrow-band that you design assuming no coupling among the resonators, expect to have to work some to insure that there really is no coupling among them in your implementation! Sometimes it gets difficult to shield well enough between adjacent resonators to get the performance you want.

Cheers,
Tom

I did take part in the discussion of matching, but I am afraid you are
off by several orders of magnitude regarding the impedance value.

Say you shoot for resonance at 1 MHz: a 2.5 mH inductor (already
impractically large) and a 10 pf capacitor (already impossibly small)
will resonate close to 1 MHz but have an impedance of 16 kilohm or so,
100 times lower than your assumption.

For 10 MHz, it would be 1 pF and 250uH, again for 16 kohm.

In practical circuits the impedance is typically in the order of
300-2000 ohm.

A typical old-style mediumwave tuning capacitor has a maximum
capacitance of 360 pF to tune about 520 kHz at 850 ohm with a 260 uH
coil.

Assuming you use a much smaller than usual 100pF variable, say 130 pF
including tray capacitance in the coil, at the bottom of the band you
will need 760hH, and get 2.5 kiloohm.

On shortwave, let's say yo want to tune a lowest frequency of 6MHz
with only 60pF all included - again, nobody does that - you need 12uH
inductance but only get 450 ohm impedance.

I did take part in the discussion of matching, but I am afraid you are
off by several orders of magnitude regarding the impedance value.

Hi FCC,
You have something wrong in your thinking, but tonight I'm not willing go
to far in
the description, Maybe tomorrow. We will use 240uh inductor and about 107pf
cap.
and assume a combined Q for the tank of 1000. and a parallel resonant
circuit.
The formula is 2 x pi x freq x L x Q. So at 1Mhz we have,
2 .x 3.14 x 1.000.000 x .00024 x 1000 = 1,507,200 ohms.
Look here http://www.crystal-radio.eu/engev.htm
There are more involved formulas, but this is close.

Hi Mike,

So, for the complete expression:
>>>25,700,000*n/Is Ohms (current in nA).
you take the same current and divide it out to yield
0.025*n
where n, as I observe (but fail to see the significance of) is a
multiplier of nearly 1.

Putting this back into the complete expression in the complete
statement:
>>>At low signal levels the RF input
>>>resistance and audio output resistance of a detector diode are equal to
>>>0.025 Ohms (current in nA).
or with temperature change:
>>>0.0257 Ohms (current in nA).

Sounds fairly trivial when we are talking about tenths of milliOhms
per degree facing into source Z of a million times that, and feeding a
load resistance that is at least a thousand times larger.

This temperature dependency, too, is something I worked with 30 odd
years ago. The temperature characteristic has been around as long as
the solid state diode. I used it specifically for measuring
temperature, as does every inexpensive electronic thermometer. My
design used a constant current LED (to indicate a complete circuit)

and a common diode in series, with that diode placed at the point of interest where temperature was a production flow variable. The voltage across that diode, minus an offset for Kelvin, was a linear indication of temperature, usually accurate to within 1 degree C, if not slightly better. The coefficient is roughly 2mV/degree C.

The one oddity I find with the original material you cite is that it specifies Is which is a reverse current, and the temperature dependency is for forward voltage characteristic curve.

Such things make me question the authenticity of these sources.

OK Jim,

I gave it a look.

I have to wonder from the start, and in the context of Xtal sets that
are usually employed for BCB, where the author decided that a typical
antenna exhibited 50 Ohms resistance and 40pF capacitance.

That was the first of a number of similarly random values assigned to
components that has me drawing up cold. From that, I have to wonder
what the value is in the practice of transforming those values.

I think that you need to ask the author. I just wanted to add some other opinions.

I would say that he used some ideal values as a place to start with. Kind of a 'what if.'

When I was a kid I used to build crystal receivers that had a sliding
tap on the coil titerally wound on a toilet paper tube and adjusting
a variable cap. every station you received had a "best " posotion for
the cap and tap and this also seemed to change from day to day or even
minute to minute. This was my first lesson in the interaction between
impedance and resonance.

Hi Jim,

There are too many indifferent scribblers to merit reading them, much less entering into a dialog when they already demonstrate a lack of communication skill. I tried that for years with Art.

Having said that, your suggested link did reveal someone who looked at the problem carefully and laid out the steps taken to achieve a result. What was missing was motivation, and a connection to reality (not being smart-assed, just wondering about the extra components decorating the schematic is all).

>I would say that he used some ideal values as a place to start with.
>Kind of a 'what if.'

The "What if" is demonstrated, and it certainly gives scope. However, ideal circuit values are far from apparent. It is just as easy to use values any Xtal set owner might find exhibited by his window screen, as contrasted starting with a full size BCB antenna with an odd reactive component tossed in for spice (excuse the pun, but it works at all levels). In other words, it takes absolutely no more effort to model what one can reasonably expect to find at home, than to go to a broadcast station and borrow their sky hook (and then antagonize the Field Engineer by tossing in a haphazard capacitor).

How do you know this author would not be interested in your comments? He has presented much more than Art has in the past 10 years.

Which components did you determine to be 'extra' and why?

You talk like the pdf had significant faults, but your reply is so vague that you don't really add anything. Please share you understanding so that

others may learn.

4874. Noise Reduction Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-19 18:46:32 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <ic6gme$h35$1@news.eternal-september.org>
Source record: 6524

Hello,

Not too sharp with noise reduction techniques.

And, too much of a Sr. Citizen now to actually build chokes, etc. myself
anymore, but would like to ask the following, please.

Have a new WinRadio Excalibur receiver, and it appears that I am picking
up a lot of noise from nearby "stuff":
Possibilities, I think, would include:

Comcast Router
PC Modem
And, a whole bunch of wal-warts which I assume are switching types.

Are there inexpensive, simple, ferrite toroids that I can clip on wires
that may help ?
Any that R/S sells that are worth a try ?

For the wal-warts, should they go on the AC input, the dc output, or both ?

Should they also go on USB cables between the PC and receiver module ?
All USB cables ?

How about the Modem to Router lead, and the Router to PC lead ?

Any part of the coax lead in from the receiving (only) antenna ?
(doubt it, but thought I'd ask this one anyway)

Any thoughts would be most appreciated.

Thanks,
Bob

On Fri, 19 Nov 2010 07:43:35 -0600, joe <none@invalid.domain> wrote:

>Which components did you determine to be 'extra' and why?

Hi Joe,

To enumerate:
Ra, 50 Ohms
Ca, 40pF
R1, 308 KOhms
D1, a selection criteria of 200nA Ir
Co, 200pF
and
Ro, 154 KOhms

The question why? you apply to me is as easily asked of the author because he says nothing on their choice, which give every appearance of being capricious.

Let's look at the last first, in the audio output we have a high frequency cutoff knee of 32 KHz, why? I can think of nothing to justify that selection that is 10 times outside of the passband.

We have an audio load of 154 KOhms, why? I can well imagine this being a piezo headset, but is it an optimal load (it would appear that the diode needs a heavier current draw than that). It is not a standard resistor value, so there must be some motivation for this value - but that is left to our imagination.

D1, a selection criteria of 200nA Ir, why? Is this a good selection, or a bad one? Again, lacking the information of motivation....

R1 appears to be inserted on the basis of an anticipated Q, a topic that is wholly absent from the computations and discussion! Why? This is the component I thought of as being "extra."

Ca and Ra have already been decried, and the Ca placement looks suspiciously on the wrong side of Ra.

>So, what values would you suggest?

I cannot imagine trying to figure out the agenda for the author. The piece is wholly unmotivated beyond being an etude of computation.

The values for Ra and XCa are infinite in possibilities. For the average BCBer with limited antenna options, Ra would typically be low, maybe an Ohm at the very highest (and probably much less). XCa would be high, maybe a KOhm (but not suspiciously high like the current 7

KOhms). As you can see, the differences from the original are considerable.

>You talk like the pdf had significant faults, but your reply is so vague
>that you don't really add anything. Please share you understanding so that
>others may learn.

Please reread my comments for praise where praise was due. If the rest sounded vague, it was entirely due to the vague material offered. Consider that also.

Further, asking me why don't I do _____ (fill in the blank), I have no interest in pushing that rock up the hill - but thanx for asking.

I am far more interested in the detector side of this, but the Xtal radio brotherhood approach this like Penitentes continuously flogging themselves in order to attain a religious high.

I would choose a quasi-digital solution with a shift ring register commutation style of detection. But that means I need a battery (ANATHEMA!!! I hear the cowled acolytes sputtering). If I use a battery I could as easily, sinfully listen to a transistor radio - and my MP3 player already suits my needs with its built in radio function.

40 years ago I worked on BaseBand sets and designed with synchronous detectors. This is all very interesting to me from my former devotion, but this XTAL splinter is rather provincial.

>Any thoughts would be most appreciated.

Hi Bob,

I clipped all of your questions because they can all be answered in a word:

Y E S

Now we can move on to "thoughts."

There are two modes for noise entry: radiation and conduction.

Radiation comes from the source "over the air."

Conduction comes from the source "through wire."

The Y E S answer snubs both at the source by putting a lot of Z in line with the generator thus reducing its drive for either mode. However, this is sometimes not enough and that is generally where the focus on conduction can pay off.

Now, when I said noise can come in "through wire," think of all the wire that interconnects your listening station, and:
Does that wire have a path to a noise source?

Break that path.

Unfortunately, the path can be obscure. One such blind spot that trips many up is the power lead, and the 19th century network called house wiring. One thing about this noise network is that it often follows a hub and spoke style of design. If your receiving station shares a breaker with the noise generator, that noise current is being siphoned into your receiver. What drives most folks nuts about trying to solve that is when they add a "ground" to their rig, the noise gets worse! To some degree this is called a ground loop.

Try moving your power plug to another socket in another room (which, presumably, is on a different breaker). A method for diagnosing where your problem is coming from is to use a portable radio as a noise detector (much as you would use a metal detector at the beach). Another method is the throw breakers one at a time and note if some noise abruptly vanishes. You will have then isolated your problem to a noise network branch.

This should keep you from winding chokes for a day or two.

> Now we need to detect and tranfer the signal to a transducer

The transducer will be the difficult part (the antenna is quite simple
compared to this). As you may know, below 150mVRFpk across the
junction, rectified output voltage drops quadratically with RF input
voltage, hence detection efficiency.

So to get maximum voltage across the junction, you need a high
impedance rectifier (that means low "Is"). Disadvantage of this is
you need a transducer with same (very high) impedance (as I assume
you don't want to use electronic LF amplification). I did my
experiments with LF electronic amplification.

If you can't find / make one in the several hundred kOhms range, you
will probably need to use rectifiers with higher Is. If so, you also
need to transform the RF impedance to a lower value to get best RF
power transfer to the rectifier.

Regarding diodes, years ago I did experiments around 7 MHz with tuned
detectors where the diode capacitance is no longer small with respect
to the tuning capacitance.

When using hybrid schottky rectifiers (that are the ones with relative
high reverse blocking voltage), strange hysteresis effects occurred in
the DCout versus RFinput voltage curve. When using real schottky
rectifiers (like BAT15, 14, etc), this effect wasn't present. I didn't
document it (only some notes), so I can't share the full details with
you.

Hi, Bob.
I had to Goggle the receiver to see what it was all about. So, now
some questions about the noise.

You have already determined the noise is continuous and repetitive by
thinking it may be from adjacent computer equipment. Does the noise go
away when you set the radio to FM? If it does, then the noise is
coming in from the antenna. If not, the noise is being picked up by
the radio chassis. Did you bond it metal radio box to the computer
metal chassis or housing? I hope you are not using a plastic cased lap

top computer.

I see the radio uses a USB connection to the computer. Do you have any other USB devices connected to the computer? If so, disconnect them all with the computer off, then turn the computer on and the radio on. Still same noise. If no, plug in other USB devices one at a time and listen for noise. If one of them is the source, you may need to get a separate powered USB expander and plug all the offending devices into it.

IF not USB related, you will need to go trough the steps of determining which accessory is causing the noise.

Are you using a standard CRT for a monitor, or a LCD monitor? The LCD will generate noise from the scanning electronics in the display panel and unless the back light is LEDs, the AC operated electroluminicent panels are quite noisy. Physically move the radio as far as you can from the monitor.

You asked for thoughts and I have one other. Except for the noise, how do you like the radio?

Paul, KD7HB

Hi all,

Thanks so much guys for the really good tutorials.
Appreciate your time in doing so.

I like the Winradio Excalibur a lot.
But, there sure is a lot to learn.

With the price of "quality" big box receivers these days, there is
little doubt that SDR receivers is the wave of the future.

I really like my JRC NRD 545 a lot, but there are some really nice
things in using the Excalibur that the 545 doesn't offer.
e.g., seeing the complete (to 30 MHz) spectum in one view is really nice.

Regards, and thanks again.

Will try playing around with some of your suggestions.

Nice and succinct Richard. Thanks from me even though I don't have such
a problem right now, because even though I know everything you said,
it's good to have it stated clearly by someone else.

I will be saving this in my archives.

One thing that nobody has stated here, YET, is...

Eith a totally software controlled receiver, you have the opportunity to remove the receiver from the vicinity of the Noisy Electronics, by removing it, and it's antenna, from the shack, and putting it in a quiet location, somewhere else, and bringing the USB back to the computer in the shack via USB Extenders, or a USB Server that puts USB Stuff on an IP Network. We use this technique, all the time, up here in Alaska for our LF/MF/HF Commercial Radio systems, due to local Network, Computer, Office Equipment, and Lighting Noise, generated in the Office spaces used by companies that need to have the above Radio Communications options. I like to use a single 10BaseT (10 Mbs) IP Link to the Remote Site, that feeds a local USB/IP Server with USB/Serial Adapters, for Serial control of the Radio Systems. We bring the audio, back via an Analog Audio/USB Converter that also connects to the USB Server. All this stuff, is OTS (off the shelf) hardware and not all that expensive. One location uses 802.11N Wireless links, for the IP connection, that is 5 miles out in the bush. Very quiet indeed. All the USB is done with shielded USB Cabling, as is the Serial RS232/RS422/RS485 connections, and the USB Server and other hardware sit inside a nice shielded box, with Power, USB, and Ethernet, run thru isolators at the box.

Just saying.....

It sounds like a simple G5RV would do what you want. You won't need
an antenna tuner for general listening -- you will need one for the
occasional hf work.

Spamhog (N1JPR ?)

It might be that you are asking for the surge impedance (Z0) of a transmission line that will minimize the SWR (wrt to the impedance of that TL) when the TL is connected to your antenna (over a frequency range). EZNEC offers a straight forward way of answering the question.

Model the antenna and request EZNEC to calculate SWR over the desired frequency span. Set the alternate Z0 to something like 200 ohms. Plot the SWR on a Smith chart with the alternate Z0 as the center. Adjust the alternate Z0 (you do not need to calculate again) until the Smith chart display is approximately centered and the alternate Z0 will be the desired Z0 of the transmission line.

It is doubtful that a TL with the desired Z0 exists.

It will be apparent to you that SWR will be high over the wide frequency range that you mentioned. As a receiving antenna for use from 3 to 30 MHz, this fact is of very little importance. It would be hard to have a receiver that has such a poor noise-figure as to be adversely affected.

73, Mac N8TT

P.S. The above technique is not applicable for relatively narrow frequency spans. Its normal utility is with LPDAs.

4890. Grounding A BNC Coax Cable End ?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-21 15:19:44 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <icbdah$bd0$1@news.eternal-september.org>
Source record: 6540

Hello,

I have a bnc coax cable from a receiving (only) antenna that ends up at
a plastic cased switch box. The box has no convenient grounding point.

I would like to ground the bnc of the coax end.

I can rig "something" up of course, but was wondering if anyone might
know of a bnc connector which perhaps has a wire lead coming out of it
for this kind of purpose, or a screw terminal, or something for
grounding the bnc shell (and hence the coax shield) ?

Looked, but couldn't find anything appropriate.

Thanks,
Bob

Bob-

The BNC crimp connector I'm familiar with has a cylindrical ferrule that first slips over the Co-Ax. The connector body is then pushed onto the cable with a smaller cylinder sliding under the Co-Ax shield. Then the Ferrule is slid back over the shield end and inner cylinder, and finally crimped.

I don't think it would be practical to insert a wire to be captured in the crimping process. Although it might be possible to solder a wire to the ferrule after it had been crimped, the Co-Ax dielectric would probably be deformed by the heat.

Does the BNC connector have a mate in the box? If so, the mate might be a better place to attach a ground wire, especially if you want to disconnect the BNC at some point. If not, you could install a female connector on a grounding plate, that has no connection to the Co-Ax center conductor.

Hi Bob,

The female BNC bulkhead connector often comes with a star/flat washer
style of solder tab.

There's also this style which is overkill for you application.
As Richard said the star/solder tab will work
http://www.l-com.com/item.aspx?id=5484
Not the best picture but, on the expanded view you can see
a ground tab with hole and the center pin.

4897. Common Mode Choke ?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-11-22 19:22:33 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <iceftr$8s4$1@news.eternal-september.org>
Source record: 6547

Hi,

Like I mentioned in a previous post, I have a WinRadio Excalibur SDR
being fed by a PAR EF-SWL antenna.

Would like to improve the S/N ratio a bit.

After the PAR Balun, I have the typical coax run to the house.

I will get some of those snap on ferrites, as suggested, and try them out.

I have tried unplugging just about all of my wall warts in the vicinity,
the LinkSys Router and the Comcast Modem.
Surprisingly, at least to me, no discernable changes.

I see WinRadio offers, for $50 (ugh), a Common Mode Choke to go on the
coax at its end, right where it joins the Excalibur module.
(see specs, below)

Think it's worth a try ? Why ?
Thoughts on ?

Thanks, and a Happy Thanksgiving to all of you folks,
Bob

"This device provides a means of reducing or eliminating common-mode
noise from an antenna feedline, resulting in a considerable increase of
the received signal quality. Common-mode noise is generated by
computers, lamp dimmers and other electric or electronic appliances.
Such noise can be a problem especially in the lower portions of HF
spectrum, where weak signals can be sometimes completely masked by
assorted buzzes and other unwanted noises.

The Common-Mode Choke can be also very useful to provide an alternative
earthing point for an active antenna, if the antenna itself cannot be
grounded due to its location, or its ground connection is inadequate.

The WiNRADiO WR-CMC-30 common-mode choke is inserted in the antenna
coaxial feedline close to the receiver, in order to "choke" off
common-mode noise currents and passing them to ground without affecting
the useful signals between the antenna and the receiver.

The common-mode choke will let through DC current, which is useful in
situations where an active antenna (for example the WiNRADiO AX-81S)"

4898. Re: Random wire vs ANLP1

I'll be sure to report back my findings.

Since posting this I've started to wonder if I really need a radio of the 7030 caliber. Thoughts on that? Am i going to find a substantial difference between something like the Grundig sat.750 and the AOR7030? Or even the little g5 portable? Seems like between this I might start to focus more on speaker quality as the reports are that they are all great radios? I'd love to hear what you all think about that idea.

Noise is the ear of the be-hearer. Characterize your problem with
noise levels observed at what time of day and in which band. If the
noise is bothersome, it is worth starting a log just so that you don't
go chasing your tail when it is merely seasonal.

Have you changed the source of power to your
WinRadio/Computer/what-ever? Use an extension cord to a power strip
that provides power to EVERY gizmo plugged into the computer
supporting your WinRadio. Plug the extension into every branch from
your breaker box.

Take note of the emphasis on EVERY! Any exception turns this exercise
into an useless endeavor. In the past when our Internet connection
went to a modem, the Telephone ground brought grief. Connections like
that can slip beneath the radar. EVERY means your antenna line too -
which is to mean it might pass through a grounded connection along the
way, and that is enough to scotch this deal.

>I see WinRadio offers, for $50 (ugh), a Common Mode Choke to go on the
>coax at its end, right where it joins the Excalibur module.
>(see specs, below)

You can find the same thing for less. You can build it even cheaper.
>Think it's worth a try ? Why ?

What's your time worth?

>Thoughts on ?

Sink a ground rod at the far end of your transmission line where it connects to the antenna. Connect the coax shield to that rod. Remember to connect that rod to your service ground through a SEPARATE wire. Using the coax shield to bring the far ground back to the shack invites disaster.

See this: http://www.audiosystemsgroup.com/RFI-Ham.pdf for lots of
explanation about chokes, filtering, which mixes to use, where some
sources of interference come from, etc.

Hi Guys,

Just wanted to say thanks for the info., and taking the time to help me out.

Have read a fair amount of the theory, understood some of it, but am the
conviction that proper grounding, noise, etc. are truly one of those
subjects that combine theory and "art" together.
Sure is a lot to learn.

Regards,
Bob

For hearing about how products perform, I put them into Amazon, and look at the customer reviews, and pay attention to the ones yelling MURDER!

For some products, those folks are lost at sea and asking for table napkins - or they are dead-on. Very easy to differentiate. When I looked at those complaining of Grundig quality, they sounded knowledgeable for some things, and hyper-sensitive about other things.

Amazon doesn't sell my Radio Shack 20-125, but it, too, finds web sites that offer a spread of reviews where, again, I look at the ones yelling MURDER! When I encounter one complaining that there was no tuning knob, I have to wonder. This sucker cost me $40, and I could easily see that feature missing before I pushed the credit card across the display case. Others complain of lack of sensitivity (I saw no evidence of them using anything but the whip). I've already heard more African stations in a day on my RS20-125 than they will in a lifetime on theirs - unless they go to Africa like I did. Another complains of bandwidth - c'mon, it is a consumer radio, not a communications receiver.

And then there is the class of disgruntled customer who grumbles about the poor fit of controls made by Chinese sources. They can find these problems with any product.

Being the type to expand upon this kind of grief, I would suspect from the from all comments considered that Grundig put a RS 20-125 inside their magnificent case which, perhaps, suffered some fit and feel problems (being Chinese made, after all - give me a break! Do they think they are Swiss Watches?). With a price ratio of 7:1, is that magnificent case something you need?

At the end of the day, you really need to visit the show room floor, look at the various models to appreciate how they are going to fit into your lifestyle - and then take them for a test drive. That is, put them on a known antenna, at the usual listening time, and listen.

Bob, seems like you have never listened to shortwave radio before. You need to understand that noise is everywhere on the shortwave bands. Many frequencies are almost and sometimes are, totally unusable, for communications to a given area. Just the last several weeks, the 75 meter band, 3980 in particular, has been so noisy after about 5pm Pacific time, that communications with stations up to 300 miles away has been almost impossible. Static crashes, and all manner of noise. But stations 800-1000 miles are clear and readable.

The same problem happens every winter to the lower shortwave frequencies.

You need to tell us what frequencies you are listening to when the noise is there.

Not yet,
I still want Richard to act like he understands that
the diode characteristics are important and the diode must be
selected to match the circuit and received station signal strength.
BTW, what is the name of the teaching method where the teacher
questions every statement made? Wasn't it named after some famous
teacher/philosopher?

But what is the practicality of getting this type of match when the
impedance of the circuit changes every time you change frequency or
any other parameter. Search for such an optimum match is truly a
"fools errand". Just one of the reason most people dont listen to the
ballgame on a crystal set anymore.

Hi Mike,

This expectation is somewhat disconnected from your earlier acceptance
of my ordering of priorities through a figure of merit methodology.
This always works, or it reveals that the designer has a poor grasp on
what is valuable to him/her. There is absolutely nothing that anyone
can do about how assessed values shift in the mind of that designer.

>and the diode must be
>selected to match the circuit and received station signal strength.

That doesn't seem to be a solution for you. If you reread my posting
that ennumerated the priorities, one of which I incompletely quote
here:
>> The detector is the variable of concern, it is defined by the current
>> necessary to drive the headset, everything surrounding the detector
>> has to conform to its choice.
then you will find it is the inverse statement you have just offered.

Focus on any other variable will present a greater dissappointment.

Hi Paul,

I guess I'm one of those folks who pretty much tunes all over the place.
Really don't have any particular bands I stick with.

My questions on how to reduce noise are pretty much generic, in that I
thought I would like to lower the noise floor (as shown on the Excalibur
spectrum) and boost the S/N ratio, a bit, wherever practical.

My thinking was if it isn't too hard to do,and expensive,it's always
worth a try to improve things somewhat.

Will try some Ferrites over some of the cabling, and antenna, in the
near future, and possibly try that WinRadio common mode choke.

Will let you know how things go.

Much thanks for the interest and help,
Best regards,
Bob

Depends what you are listening to. AM broadcast, almost anything
will work. SSB, and weaker utility stations, a better receiver can pay
off. Not so much sensitivity, but filtering, image rejection with
larger
antennas, etc.. Often more stable too..
I've got loads of receivers, some of which I never use and forget
I even have.. IE: I've got three or four "portables", but never use
them.
But for SW/MW-BC, I could pick up any one of them, and have
no problems with a little more wire clipped to them.
But most of the reception I do is SSB, and listening to other
hams. So naturally, I usually prefer a bit better radio with
better selectivity. Some of my cheaper portables don't even
have SSB mode.. Some do though..
I've got several Drake receivers. The cheapest one being a
Drake SW-1, which does not have SSB capability.
But it's great for casual SW-BC, and MW-BC. It's S/S
and can run off 12v.
But useless for ham use, except for maybe catching a few
AMer's. For SSB use, I'd be grabbing one of my older Drakes.
Or.. maybe if I were trying to dig out some weak station
packed in between a bunch of powerhouses.
I've got a Drake 2C and 2 CQ, one of the original R4's, "0058
serial", and also a R4C. I've got one of the very first R4's built,
and one of the last.. :/ Both are pretty good radios.
My little IC-706mk2g is great for almost any kind of listening.
It's filtered tight enough for average SSB, but it's wide in
the AM mode, unless the filter is on. So the AM audio
sounds real good on it. The AM filter is actually too tight,
and almost useless so I almost never use it.

One thing I like about it, is it's general coverage and goes
up to UHF. So I can listen from LW, up through MW/SW
and on up through the air band, police bands, etc..
Makes a great scanner.
So many receivers, so little time.. Or money in some cases..
:/
You just have to decide mostly on what you want to
listen to.

Dear Filippo N1JPR: You are welcome. Indeed a scheme does exist to find
the ballpark least-bad Z0 given constraints.

For several sufficient reasons, you will find that using EZNEC is desirable.
All sorts of "what if" designs can be evaluated.

73, Mac N8TT

BTW, the Grundig G6 Buzz Aldrin 40th Anniversary edition is on closeout
at Radio Shack. It's smaller than the name.

I couldn't resist myself. So far the best half-a-pocketbook sized radio
I've owned. Good AM filter width.

Actually it's the smallest multiband radio I've ever owed by about a
factor of 2.

Hi Tom, Did you ever try anything with that NVIS antenna. I think I am going to put up one permanent in back yard, turn the RV into my ham shack or dog house whichever description is appropriate at the time.

This guy carries 30 pounds of tools up the ladder with him? Most climbers I know take the end of a line with them, then attach a pulley where they'll be working, then they send the end of the rope back down. Then the ground crew can send up tools, parts, whatever, and you don't have to worry about not forgetting anything but the rope and the pulley.

Maybe he works alone...

The climbers you know probably climb 100 ft towers?

With this tower that would require 3,400 ft of rope, which probably
weighs more than the tools and will be very difficult to handle.

The climbers you know probably climb 100 ft towers?

With this tower that would require 3,400 ft of rope, which probably
weighs more than the tools and will be very difficult to handle.

Not to mention the extreme likelihood of the rope getting blown around
and/or snagged on any of dozens of appendages (microwave antennas, FM and
comms antennas, tower lighting, etc) that are on such tall structures.

You take a messenger rope (3/32") up with you. Once through the pulley
and back down that rope is used to lift a more substantial rope, all
done by the winch on the service truck. This is a safety feature. People
cramp up sometimes.

You usually have a ground crew person feeding the line and watching such
things. California has stricter laws than OSHA. I think you have to clip
on when climbing here.

I first discovered NVIS of sorts although I didnt know what it was
called back in the early 70s with 11M radio. I found that a homemade
1.25 wl antenna would often work areas during skip conditions that
were different from my 5/8 wl antenna. Some were in the neighborhood
of 100 miles away which was unusual for a CB. Normally you couldnt
hear anything from 30 miles out to about 300. After 300 you could pick
up skip signals.

9mm static line weighs 57 gm/meter. A 1000 meter loop would weight
57kg or 126 lbs. No thanks. Also, the line has quite a bit of wind
resistance and will probably cause the 30 lb tool bag to sway quite a
bit in the wind. However, since he rode the elevator almost to the
top, he might be able to handle a 50 meter single static line to the
top of the elevator.

Nice video. I wonder what they were repairing on top of the tower?
Replacing the tower light?

Press Release

Tower Association Responds to Erroneous and Dangerous Video

The following statement is being issued by the National Association of
Tower Erectors (NATE) regarding a dangerous video post erroneously
characterizing ï¿½free climbingï¿½ on towers as lawful and common.
NATE would like to publicly denounce the message of the recently posted
video depicting two men climbing a broadcast tower. NATE asserts that
the posting of the content was misguided and its messages should not be
given credence by any viewer.
The ï¿½Stairway to Heavenï¿½ video, reportedly launched by
TheOnLineEngineer.org, suggests that free climbing is an accepted method
of ascending and descending broadcast and telecommunication towers. The
video incorrectly asserts that free climbing is accepted by OSHA and
that ï¿½most tower workers climb this way.ï¿½ The video also depicts as
standard procedure other dangerous and prohibited conduct not condoned
by NATE or OSHA. There are many inaccuracies in this video.
NATEï¿½s efforts to establish a culture of safety in the wireless and
broadcast tower industry encourages everyone involved with tower work to
adhere to recognized safe practices. The video in question is an example
of a climber who is either unaware of recognized safety practices or is
unwilling to take the time to protect his life and the life of his
co-worker in the video. By extension it encourages others to employ
unsafe climbing techniques not endorsed by either OSHA or NATE.
Contractors who refuse to operate safely should never be hired. This
video is one more example of why the efforts of NATE, our membership and
industry partners are imperative.
NATE, the industryï¿½s leader in tower safety, continues to pursue working
relationships with carriers, broadcasters and other tower
owner/operators to ensure that only qualified contractors set foot on

tower sites. The Association has worked with OSHA to develop safety best practices and educational programs to ensure every tower worker goes home safely every day. Companies which allow free climbing and other violations of recognized safety practices are placing lives in danger and jeopardizing tower work services.
NATE is looking forward to OSHAï¿½s statement clarifying this matter for the industry.
Work Quality in Question
Employers who allow such practices will likely cut corners on other aspects of their work. NATE asks, ï¿½If a company or employee will cut corners with the lives of its workers, on what other aspects of work will they be willing to cut corners?ï¿½ Owners and operators who hire this type of contractor are opening themselves up to legal and regulatory actions and are additionally running the risk of system malfunctions, adding unnecessary costs on top of endangering lives.
NATE Requests Contact From Tower Owners and Operators
NATE is requesting contact from carriers, broadcasters and other entities who own, operate or control wireless and broadcast towers as well as the industry groups who represent them. NATE is doggedly pursuing working relationships with these organizations to ensure that a culture of safety exists throughout the industry and that only qualified contractors set foot on tower sites. If your organization fits this description, please contact Patrick Howey at 888-882-5865 or patrick@natehome.com.

yeah, and you'll probably see it brought up every few months for quite
a while now when someone new finds it for the first time.

I have a Homebrewed SWR meter I was thinking of calibrating it to read power by appling a dial for the "full scale adjust" potentiometer. Meter would be initially calibrated against a know accurate wattmeter. Variable HIgh Power RF source would be an Amateur band SSB TX modulated by a single tone audio source. Power varied by adjusting the level of the tone. Power would be read from the dial pointer. One thought is to use a difference meter reference for each ham band .... 10M full scale 15M a little less. Any thought s on this method would be appreciated.

Jimmie

Provided you calibrate it, the meter should be able to 'dual-task' as a
power meter. An RF power meter is really only an SWR meter which is
calibrated accurately in power.

The variation of the SWR meter's sensitivity from band to band depends
on which type of circuit it uses.

If it's the 'old-fashioned' type, which uses a short length of
air-spaced coax with an additional wire inserted as a coupling loop, the
sensitivity increases significantly with increasing frequency.

If it is of the ferrite transformer type, the sensitivity should be
pretty constant on all bands, and that is the best type to use for power
measurements.

dr Jimmie,

From your last remark I guss that your SWR meter bridge principle consists
of some kind of coupling pick-up loop where the RF output versus frequency
is not flat but follows a +6 dB/octave characteristic, i.e. more sensitive
as the RF frequency rises.

In that case you have you have two options: Calibrate the meter individually
for each amateur band or pass the coupled RF through a -6 dB/octave low pass
filter beforde detection.

It might be easier to add to your SWR meter a separate RF detector to sample
the RF at the main line. This is easily made (mostly) frequency independent
and it can be calibrated separatey from the SWR part. You will of course
need to add a switch in order to change from SWR to power readings.

Yes Ian it does use a piece of coax for the pickup. It should be a
simple matter to modify it to the ferrite transformer type.

Thanks

In which case, I would suggest a spot of Googling, or searching in the
usual handbooks. [At one time, every handbook had at least one article
on a DIY RF power meter.] There are many variants of the circuit, and
their complexity varies.

I've had a quick Google myself (eg 'rf hf power swr meter'), and at first, it seemed surprisingly difficult to find anything really basic. However, the inclusion of 'wattmeter' was much more successful. These are some of the hits:

I have been struggling with this for some time
so maybe somebody can set me straight.
We wind a flat plate spiral antenna and we get to a point where the
center medium becomes saturated with flux.
Now I add even more coils. What action does that precipitate? I would
like to think that the Meissner effect (perfect diamagnetism) then
takes over and swamps the external magnetic field as with a
superconductor (ie opposite to that of a paramagnetic) The skin
effect is thus removed allowing the current flow to the surface by
allowing the atomic structure to relax, and add to the current already
in place to allow fully efficient radiation as it now lies outside the
confines of conductor resistance.
This is my effort in determining what is it that drives the constant
impedance attributes of a meander type array?
Regards
Art

no meissner, no diamagnetism no swamps no paramagnetics
no relax, no outside,

Whatever.

Those broad band antennas work, that's for sure,
without your ingredients.

Are you questioning your effort, or all the false
theories you are conjuring?
For you to truly see the light, you will need to build one
of those antennas, and then do A/B comparison tests
against a known benchmark such as the dipole.
The fact that you will never even approach the efficiency
of a dipole will then dissolve all your other theories into
leftover turkey casserole. We could call it "Meander Casserole"
if one were desiring to patent it and publish the recipe. :/

Thanks Ian. Found one in my junk box with a little postage stamp sized meter(broken). Removed the innards from it replacing the the reflectometer in the other unit. This pickup seems to have a lot more output than the old trough type that was in it. Will have to play with some resistor values to get it to play well with the metering circuit.

If it is the type where calibration varied with frequency, you could copy what was done with some commercial instruments of the seventies, eg the Oskerblok.

1. Calibrate the sensitivity knob with a logging scale.

2. Add a power scale to the meter face.

3. Measure a set of points of sensitivity setting vs frequency where the meter scale is correctly calibrated for power.

4. Create an interpolated smooth graph as a lookup, and attach it to the instrument.

Be prepared for significant linearity error at the low frequency end if you calibrated the meter for low fsd power.

If it is a Bruene type sensor, the response should be reasonably flat within a frequency range which you must establish.

The interesting thing with either type of sensor (and both are used in Bird elements, though the first type is frequency compensated), is that although the Pfwd and Pref power readings are of each of no value by themselves, the power in the line is Pfwd-Pref irrespective of the load impedance or line Zo.

As a furthur background to the question.
I modelled a two coil spring to make a closed circuit. Running thru
the swr vs frequency I find that when I get into the Ghz realm the
anti resonance value migrates to 52 ohms with low
reactance escursions. Later the resistance value drops to single
digits and then fraction of ohms together with slight reactance
escursions
with R being less than the wire used. At the same time gain shot up to
the high twenties in cyclic form but with the extremely low impedance.
The current flow at the feed point was 100% surge quickly dropping to
a constant 25% current flow .I then made a 5 wire tape
very close wound pancake about 24" dia which I placed inside a bowl
shield which was grounded. This provided a fairly constant impedance
with what appears to the ear to be a doubling of more of gain against
a quiet background. I have nothing else to add except the computer
program does have a precipetous drop in impedance which sort of
alignes with superconductors when it changes over to perfect
diamagnetic, where skin factor of the conductor is removed allowing
current flow outside the conductor as shown by its low impedance. The
pancakes (stacked) with short length compared to a linear solenoid

are fed at the center where surge current is at its highest and where all wires tape ends are electrically connected together to complete a closed mesh type tape. The same can be done with a 100 foot roll insect window mesh with the material backed by thin duct tape.
Thus the point of the question, What propels
the reverse swamping of the previously weak
diamagnetic fields?
Thanks for looking
Art
With the current leaving the conductor the two vectors for the most efficient elevation and thrust (are vector with heliical spin) to the surface residing particles as shown by Gauss which also aligns with Maxwell.

One thing I should mention is when the "surface" current flow begins
the radiation pattern goes thru a 90 degree phase change(a connection
to the EH driven antennas perhaps?)
I am now re writing the program with the x and y coordinates
interchanged to see if some clues
come to light when f/b and gain figures change from the X to the Y
axis

Owen, the meter is just a 1 to 100 linear scale meter on on 100 uA
movement. Ive used it for years just to "guesstamate" VSWR. Not really
as inaccurately as one may think. My thought was to cal a scale for
the "full scale set" knob so that when the meter is adjusted for full
scale the knob position will indicate power. Part of the reason for
doing it this way is that it is a nice large good quality meter and I
dont want to risk damaging it by taking it apart. I may have other
uses for it later on. Im thinking "linear scale capacitance meter
similar to the heathkit model. I intend to use an NE555 osc instead
of vacuum tube osc should I do this .

Hi Jimmie,

On reading this, several thoughts came to mind. You write about
having used a linear scale to guesstimate SWR. Sounds good and it
immediately leads us to an existential question:
"What value is there in knowing the value of SWR?"

The first motivation following a glance at the SWR meter is to LOWER
the SWR, for whatever value it may reveal. In this sense, the value
is a trivial consideration - relative indications are enough to
achieve the goal.

Using the feed from a Bruene style detector pair into a Log-Amp will
give you a power response in a linear scale. If you want to know the
SWR with accuracy, you can throw the reverse switch for the second
power reading and compute, or you can throw the reverse switch and
start twisting nobs to make the power indication go away.
consider:
http://rfdesign.com/mag/503rfd33.pdf
Says it all in one page - with pictures, schematics, and math too.

I don't quite catch the drift of the "capacitance meter" paired up
with NE555 osc. I presume you mean to construct a DC-Freq converter?

Heathkit made a linear scale capacitance meter years ago dont remember the model #. CM? I think. Circuit use a tube in a multivibrator configuration the NE555 is just a more modern approach to th same circuit. Cap to be tested is in series with the osc and meter. Current through the circuit is a linear function of capacitance or for that matter frequency. I never got around and may never still build the circuit because I can always bread board a little circuit to use with my function generator when I want to measure a capacitor. I cal the circuit using some precision caps before use. I agree with your view of usefulness of knowing SWR. I use it mostly as a relative health indicator of my antenna system. . A high SWR on my 40M dipole may indicate something is not well and I should look out the window while an unrealistically low reading on 2M probably means I have water in my coax.

BTW the reason I bought the little home brew SWR meter was to source the meter and box for this project. My lack of real need for it has kept the little hamfest treasure an SWR bridge.

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

If I have followed the thread properlty, you have a VSWR meter and you have now decided to replace the coupler. The meter movement is actually intended for another project.

It might not have occurred to you that if the diode voltage drop is small wrt the RF voltage being rectified, that the 0 to 100 meter scale could be taken to be rho (the magnitude of the complex reflection coefficient) in percent. But, there is an if in there, verification is needed.

The calculator at http://www.vk1od.net/calc/tl/vswrc.php accepts rho as an input (it is called the voltage reflection coefficient in the calculator). So, if you were measuring SWR and you had 'set' the fwd direction for fsd, then read for example 15/100 reflected, rho=0.15 and the calculator will tell you that VSWR=1.35.

If you think that the entire content is captured in your summary, you
aren't as clever as you think.

Jimmie and other readers might glean more from it than you apparently did.

These might not be regarded as cheap, but they are designed for purpose:
http://www.tet-emtron.com/product-p/te-450sp.htm . They are not 4 to 5
inches wide, the seller claims about 450 ohms using 2mm diameter bare wire.

If you used insulated wire, Zo would be a little higher (eg 1mm conductor
would give somewhere between 500 and 600 ohms).

Yes I missed some words ! It wasn't very clear at all.
I should have said that the reverse power would be 3:1 at half scale.

The point being that if you adjust forward power for full scale meter
reading then 3:1 reverse power will be at half scale, 2:1 quarter scale
etc.

"then 3:1 reverse power will be at half scale" is gobbledegook.

Would you like another guess?

If diode voltage drop is insignificant, quarter scale (rho=0.25) equates to
VSWR=1.67.

True enough, but checking SWR isnt my main concern I can interpolate
that well enough. I was just wondering if my idea for measuring power
via a calibrated full scale adjust dial would be a valid procedure.

You could do it the way you describe. The question is not whether it can be done, but rather what the expected error is. Meausuring RF power is a challenge, and adding the potentiometer setting as a variable element adds error. That was a weakness with the Oskerblock sheme I mentioned earlier.

I don't really understand the issue with the meter. I see meter movements on Futurlec for $10.

An alternative approach is to use a DMM with a lookup graph to interpolate detector voltage to power. So, you put a jack on the instrument to pick of the DC from the fwd and rev detectors, and do up a cal chart relating that voltage to power.

I have added a 1/4" TRS jack to a commercial VSWR / Directional Wattmeter doing just that, and have created a cal chart in a spreadsheet that allows cubic spline interpolation for high resolution power measurement. Whilst improving the resolution doesn't improve absolute accuracy, the high resolution capability is really handy for some tests.

An article describing the technique is at http://www.vk1od.net/measurement/irpm.htm , and it includes a link to the spreadsheet which has the cubic spline interpolation feature.

These days, unless you're deliberately trying to retrofit, you'd be
better off with a scratch design using the very nice Analog Devices RF
power detector chips (huge dynamic range, temperature compensated) and a
microcontroller to do the calibration for directivity. A fancy one
might even attempt measure the frequency and do that part of the cal as
well.

Once you're not trying to go directly from detector device to a meter,
you can do a lot of useful stuff. If you still want a meter needle, have
the microcontroller put out an analog signal.

It would probably even be cheaper than trying to make a really flat
coupler with good directivity.

4977. homemade balun question

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-02 12:24:04 UTC
From: "Geoffrey S. Mendelson" <gsm@mendelson.com>
Message-ID: <slrniff3u1.456.gsm@cable.mendelson.com>
Source record: 6577

I made a 300 ohm twinlead folded dipole that is resonant at around 15mHz.
It was cut because I wanted to try some 20m operation with an indoor antenna
and that fit exactly the space.

The ham I wanted to reach was km away, across a valley. I figured with a
tuner and a few watts, I could reach him.

I never used it for that, he moved before we ever got together.

I put the antenna up outside to use for an SWL antenna. It is fed with
about 6 feet of twinlead and then 75 ohm coax. It worked best at 15mHz,
and slowly degraded as frequencies got lower. It was useable at 7mHz for
reception.

At MW frequencies it's basicly a noise pickup and no signals could be
received.

I made a balun from 9 trifilar turns of wire that I had (.5mm plastic
insulated). The instructions I was following said to use 10 turns of
#14 enamel on a wider core, but 9 were all that fit on the core I had.
The core is 8mmx80mm with a permeability of 400.

When I hooked it up to the antenna, I found that the resonant frequency
shifted to 14mHz. My guess is that the feedline now is part of the antenna.
However at 7Mhz it is totally dead. So dead that a signal that reads S5 on
my receiver using a 2m JPole hung from the near end of the folded dipole
as an antenna does not move the s-meter at all. The null extends from
around 6950 kHz up to around 7300.

The question is why and what can I do to improve it?

Is it because there is null in the system because it is resonant at 14mHz and
it is unresonant at 1/2 of that? Is it because the balun acts as a 7mHz trap?

I now have some cores that are 8x140 and 10x200. If I make a balun using the
same wire (enamled wire is not available to me) with a different number of
turns, will it behave differently? For example, if I make a balun with a few
more turns, will the null move down?

My guestimate is that I can get 15 turns on a 140mm rod, and 22 slightly larger
ones on a 200mm rod.

How far down can I go? Will moving it down affect upper frequency response?
Can I move it down far enough that the balun will do something useful
at AM broadcast frequencies?

Some of the 10mm rods were broken into pieces in shipping. Does that affect
their performance? Can I just use the pieces as they are?

Thanks in advance,

Geoff.

These signal reports sound more like issues of propagation than issues
of the antenna. In other words: normal.

>I made a balun from 9 trifilar turns of wire that I had (.5mm plastic

>The core is 8mmx80mm with a permeability of 400.

You say instructions, but instructions for what (to what end, to what
purpose)? Why trifilar? This is suggestive of a voltage BalUn, which
is not going to give you the choking action you need to reduce noise
problems.

Keep your BalUn as is (I don't think it is going to materially improve
anything) and add a W2DU style to its input.

>When I hooked it up to the antenna, I found that the resonant frequency

This still sounds like the vagaries of propagation. Do you keep logs?

>The question is why and what can I do to improve it?

Your lead out to the antenna could have a short/open in it. I presume
you use your tuner, however of late I have been given the impression
that SWLers of this generation sneer at it in favor of the magic
BalUns they chase on the Internet (given you are a frequent poster
here, I give you the benefit of the doubt).

>Is it because there is null in the system because it is resonant at 14mHz and
>it is unresonant at 1/2 of that? Is it because the balun acts as a 7mHz trap?

The electrical properties are unrelated to the pattern properties. We
speak of nulls in a pattern.

If you are referencing a null in tuning, then that would occur at
either resonance, or anti-resonance (broadly speaking). If this is
your intent, then, yes, "nulls" would represent impedance matching
issues which in turn would put a block to signals. A tuner is a
design tool for this situation.

>I now have some cores that are 8x140 and 10x200. If I make a balun using the
>same wire (enamled wire is not available to me) with a different number of
>turns, will it behave differently? For example, if I make a balun with a few
>more turns, will the null move down?

Uhhhh. We need to decouple "null" somehow, from the discussion, or
give it a more descriptive treatment.

You describe a problem that is binary:
I used to have signals
I don't have signals
what you describe in fumbling with turns ratios is a continuum:
I used to have booming signals
I have weak signals

BalUns are not used to offset/fill/sharpen nulls of any type.

>My guestimate is that I can get 15 turns on a 140mm rod, and 22 slightly larger
>ones on a 200mm rod.
>
>How far down can I go? Will moving it down affect upper frequency response?

Solve your problems one at a time.

>Some of the 10mm rods were broken into pieces in shipping. Does that affect
>their performance? Can I just use the pieces as they are?

Magnetic performance is impacted by air gaps. In some situation this
is an asset where saturation is an issue. Super glue the pieces for
the closest fit.

Well, it stretched from one end of my apartment to the other. It just happend
to be slightly short of a 20m folded dipole.

It from a book "Simple, Low-Cost Wire Antennas for Radio Amateurs" by
Coan and Orr.

It's not needed. I have two coaxes going outside, one to the folded dipole,
one to the J-Pole. If I tune in a station in the "dead" range (7.0-7.3mHz),
using the J-Pole as my antenna that reads s-5, when I switch to the folded
dipole, it barely moves the s-meter at all.

> Your lead out to the antenna could have a short/open in it.

Possible, but at 14mHz, it comes in great, far better than the J-Pole.

> I presume
> you use your tuner, however of late I have been given the impression
> that SWLers of this generation sneer at it in favor of the magic
> BalUns they chase on the Internet (given you are a frequent poster
> here, I give you the benefit of the doubt).

It was an experiment. I was hoping to use the antenna to transmit too, and
can't run twinlead out to it. So the compromise was the Balun at the far
end of a coax. I can't say if it worked at all, I never got far enough to
try.

> The electrical properties are unrelated to the pattern properties. We
> speak of nulls in a pattern.

My bad, I was speaking of a null, as in a frequency range with zero
(or close to it) signal.

> If you are referencing a null in tuning, then that would occur at

Thanks, that's easy to try. Would it work on the near end of the system?
radio -> tuner -> 10 meters of coax -> balun -> 300 ohm feedline -> 300 ohm
folded dipole.

> Solve your problems one at a time.

Thanks. that's a good idea.

>>Some of the 10mm rods were broken into pieces in shipping. Does that affect

> the closest fit.

Sorry, I wasn't clear. Someone on another mailing list said that breaking
a ferite rod could magnetize it. I don't want to glue them together
again, I would use the pieces as they are.

Maybe a better question would of been to start from the begining and ask "I
have a 300 ohm twinlead folded dipole resonant at 15mHz, with an aprox 6 foot
twinlead feed line. I need to feed that with 10-15 meters of 75 ohm coax.
How do I get that to appear resonant to my transmitter on 14 mHz, and hopefully
7 and 28 mHz and get some signals in and out?".

Thanks and 73,

Geoff.

You are trying to get a lot from a 20m dipole. And that feed line
setup just complicates things and adds undue loss.
Myself, I would start over from scratch if you really want to
transmit on all three bands. Are you limited to the size of
the dipole? Do you have to use coax?
As far as receiving lower bands, I'd try unhooking one leg
of the feed line. Just feed the center conductor. That
should cure the dead antenna problem as far as just
listening on the lower bands.

I think I would not go with a folded dipole and balun. Especially if you
want to use it to transmitt with.

If you do not have enough space for a full size antenna you may want to try
what is called an inverted U antenna. YOu run the horizontal elements as
far as you can and drop the ends down. Somewhere I saw a way to stack
several like this for multibands. It is difficult to make a dipole operate
on a much lower frequency. That is if you cut one for 20 meters, it is
difficult to make it opwerate on 40 meters.

> Those who cannot remember the past are condemned to misquote it.

Hello Geoffrey.

I think the problem is in the folded dipole. It works as long as it is in resonance (so that current in all wires is in phase). At half the frequency, it will behave more like a halve wave loop with very small loop area (as the wires are in parallel). This is not an effective arrangement. Maybe you can try to cut the short (so it becomes an open dipole with non-straight halves).

When you live in a quiet environment, a 4:1 or 9:1 balun will increase both signal and noise for frequencies below resonance (so that antenna noise exceeds your receiver's noise).

Regarding the feedline between antenna and balun. If the balun does function well, the feedline will not contribute to the radiation pattern (current are opposite), but it will provide impedance transformation, so it becomes part of the tuning (hence resonant frequencies).

From your balun description, I can't figure out what you have in your hands Maybe you have link to a description you followed. I prefer baluns that provide common mode suppression so that when there is some asymmetry in the system, the coaxial feeder doesn't become part of the radiating/receiving antenna structure. A guanella type balun wound on two magnetically separate cores/rods does provide common mode suppression.

Regarding ferrite rods (for a 4:1 guanella balun for example), if the broken surfaces still mate closely, just use some liquid adhesive and join them. As most of the field lines go to air, effective permeability doesn't change practically.

For making a really wide band balun, you need the right ferrite material. For wide band applications I use, for example, fairrite material 43 [ur=800] (material 31 [ur=1500] would be better). You need a material that has high permeability at low frequency and also reasonable permeability at high frequency. Many power ferrites have good permeability at low frequency, but it drops rapidly at increasing

frequency.

If your choice is limited, try to get ferrite material indicated for HF (1.. 100 MHz) EMI suppression. As it is for reception only, I would not go for rods, but toroids. Toroids provide higher inductance at low frequency because of the closed magnetic path (so you need less turns).

Regarding MW broadcast reception. I get best results with vertical polarized antennas, so your dipole may not be good for this.

Best regards,

Wim

What happens after the magnetic field is saturated is excess energy
then goes to increase the electric field which is enclosed inside a
shield or Faraday cage for maximum density which produces two vectors
equal to the two vectors created by gravity and spin as shown with the
tipped vertical. These vectors arise fro a diamagnetic condition when
the electrical field achieves satuaration or maximum density with a
Farady shield.
The importance of these two vectors is that we have the displacement
vector which elevates particles or electrons at rest on the coil
wire,.
It is this vector which is equal and opposite to gravity that allows
for ":straight line trajectory" of the negatively charged particle
such that the other vector is free from constriction in all forms
which is synonomous to equilibrium.
Thus a solenoid can be seen as a radiator according to Maxwell where
the magnetic vector is canceled for maximum efficiency.
This also shows that the previous two element design where both
elements are resonant within a boundary which must be included as a
shield around the two element array for maximum efficiency.
I find it completely fascinating that the two vectors I propose as
Einstein's predicted version of the Standard Model turns up once again
in this solenoid version of a radiator within a Faraday cage to which
a horn is easily added.

So this thread now comes to closure
Regards
Art

Hi Geoff,

That confirms propagation - more a matter of polarization. We keep a
variety of antennas to suit just situations. Polarization diversity
is what that is called.

>> Your lead out to the antenna could have a short/open in it.
>
>Possible, but at 14mHz, it comes in great, far better than the J-Pole.

I presume by this response, your antenna/line being "dead" at 15 MHz
(it should be a busy band) is quite alive at 14 MHz (which, too,
should be a busy band).

>My bad, I was speaking of a null, as in a frequency range with zero
>(or close to it) signal.

The following is pedantic for its own sake:
Null in engineering denotes the indication offered in a balanced
situation - the meter indication in a bridge - where two potentials
are equal (no current flows in the meter). As you adjust the arm on
one side of the bridge, the approach of equality reduces the potential
between both side of the meter, and its indication "nulls."

>> If you are referencing a null in tuning, then that would occur at

That is good solution; the perfect topology would have the tuner at
the 300 Ohm folded dipole with coax back to the radio.

Someone on another mailing list has mixed priorities. So what? (Not
to say I buy their guff.)

Feel fine to use them as they are, but if you were to use them as
stock for choking purposes, more bulk ferrite offers more bulk
isolation.

>Maybe a better question would of been to start from the begining and ask "I
>have a 300 ohm twinlead folded dipole resonant at 15mHz, with an aprox 6 foot
>twinlead feed line. I need to feed that with 10-15 meters of 75 ohm coax.
>How do I get that to appear resonant to my transmitter on 14 mHz, and hopefully
>7 and 28 mHz and get some signals in and out?".

The fold in the dipole, the approx 6 foot twinlead feed line, the 75
Ohm coax, and the BalUn are unnecessary elaborations. The combination
of all sounds like complexity squared to achieve a goal by applying
nebulous charms.

Resonance is resonance and the rest is unnecessary. You put up an
ordinary dipole, connect an ordinary line to it (OK, so it can be 75
Ohm line if that is what is handy) THROUGH a choke (AKA 1:1 BalUn),
and to a tuner at your radio. The tuner solves resonance. Sometimes
a tuner cannot cope with extreme natural resonances such as a fullwave
dipole presents you on the band you want. Cut the size of the dipole
and move on.

The combination of folded dipole, odd twinlead line, and high ratio
BalUn (almost always of the wrong construction) suggests the desire
for an "all band antenna." That and unicorn horns for aphrodisiacs
are sought by many and claimed real by liars or fools. Marrying the
term "resonate" or seeking resonance from these antennas compounds the
lie or the foolishness.

The usual (and inverted wish from seeking resonance) is that this
solution of dipole/tuner dashes the SWLer's desire for frequency
agility (no time to tune an optimal signal when chasing the bands).
The simple solution is the Fan Dipole. This new solution being too
easy and lacking the mystique of charms, amulets, and complexity to
fuss over, SWLer's quickly reject simple success to cozy up to the
oddities of their failure in contrast to the glowing (lying or
foolish) reports of others (liars or fools) using the (presumably)
same contorted design.

It's not like any of these contorted designs bring any gain to the table. And the gain differences between them and a simple dipole wouldn't move the S-Meter more than a needle's width!

The reason why I am quick to dismiss "frequency agile" requirements is that I know full well that SWLing demands your full attention on one frequency to pick up that interval ID signal, or just recognize the style of programming if you are going to catch that DX. The agility race is won by the patient listener.

However, if you really want an "all band" antenna that is "frequency agile" then the Fan Dipole will do that on every band you cut an element for. All it takes is wire (and it would seem you, and others, made that investment with the fold).

Hi,

I newbie in antenna area. Currently, I'm trying to design a folded
dipole antenna. Thus, I need some ideas on how to design that antenna
such the dimensions, length and others.

Please help me. Thanks.

Art,

Shirley, you can't be serious! (with apologies to the late, great Leslie Nielsen). Sincerely, and 73s from N4GGO,

Yes, I am very serious about my findings. I am very sorry that others are unable to follow my same path to obtain the same joys of discovery.
For some reason people cannot fathom the idea of equilibrium and that displacement current provides the equal of the gravity vector.
There is no way a charge can travel in a straight line up to the heavens and down again
without the neutralisation of gravity and without the auspices of spin . The same goes with respect to light according to the Zeeman effect

I found a five page article in the Sept. 1982 QST by VE2CV and W1FB,
titled "The Half-Delta Loop: A Critical Analysis and Practical
Deployment." It is just what I was looking for -- a real analysis
with formulas, charts, graphs, and diagrams. Well, I just got a
couple hundred feet of antenna wire and some insulators. All I need
is some lousy weather to put this thing up!

I am not dreaming! The magnetic field increases density until it
reaches a maximum.
The curve of B vs H clearly shows this in a similar curve to Hooke's
Law for strength of materials. At the point of saturation the value of
B comes to a halt and where H takes off and increases rapidly. I would
imagine that if you searched the web under saturation magnetic fields
or some other similar key words you will eventually find verification
of what I have described. You might want to search under diamagnetic
because you eventually come to the point where diamagnetic field
predominates which puts you in the same position of superconductor
where skin resistance is removed. I am extremely surprised that as a
electrical engineer you never covered magnetics in depth. If you find
verification on the absence of saturation in magnetic fields I will be
more than happy to apologize for my lax memory of my early days. Up to
now tho, you have never produced evidence or any reasoning to back up
your comments or status as an electrical engineer, scientist or what
have you!. Was it ever explained to you that levitation
by fields is exactly equal in direction and value
to gravity? How do you explain to amateurs how "straight line
trajectory" is attained when explaining skip or are you going to deny
that also? I look forward to reading your back up
research statements that support your positions.
Regards
Art

How does one neutralize gravity? The anti-gravity of comic books?

Let's see, the energy of an electromagnetic interaction is
1000000000000000000000000000000000000000 times greater than gravity.

So, when an electron pushes a charge against gravity, it has 400dB
more effect than gravity pulling back. In comic book terms, that is a
Thousand, Billion, Billion, Billion times stronger than gravity.

An ant weighs 0.003 grams, and the Earth weighs 5.9 x 10^27 g, so you
would need 10000000000 planet Earths to replicate the neutralization
between the energy of gravity and the energy of electromagnetic
interaction (assuming the ant was an electron of ant-like proportions,
energy-wise).

Such is the sandtrap of neutralization across units of measure. It is
much like the folks of 100 years ago claiming a car couldn't drive up
a hill without a warp drive engine with a dilithium crystal controlled
gravimetric field displacement manifold.

As we all know (or almost all), Gene Roddenberry is the authority to
turn to on the basis of this last claim being fulfilled some 50 years
from now by Zefram Cochrane developing the first warp-capable
starship. How we currently get to the top of hills in a car is
considered as an example of superstitious mass hysteria.

We can all rest assured that this meets the criteria of not coming
from any text book because it hasn't happened yet. *Whew* Hence, it
cannot be disproven. Don't rush to the patent office however, this is
considered Post-Art.

Just rubbish
You are just being foolish. Have you never elevated anything using
magnets? If you haven't then buy a kit to see it for yourself.
The same is used in many places in science

and Industry where transport is raised to avoid friction. I warrant that you probably can see same on video on the net or a frog suspended in air .
If you cannot neutralize gravity then you cannot have straight line trajectory. Period. When a particle is raised from a surface then you do not have to account for friction when propelling
or accelerating it. Thus all energy applied is used solely to achieve radiation without the burden of friction created by skin depth which is not accounted for in Maxwells equations as it reduces efficiency.
As I said at the beginning you are just acting silly or being a fool.Or, have no understanding of the term equilibrium or Newtons laws for that matter. Now a question, Why did Maxwell use the term "displacement current" and what was he suggesting what was being displaced from the control of gravity? Now get going, collect a lot of random words. Put them in a container and shake it and pull out a word at a time as you normally do with any written response.

you are looking at curves for ferromagnetic materials that do have a
saturation level... the point where all the magnetic dipoles in the
material are lined up. for your quick browsing enjoyment:
http://en.wikipedia.org/wiki/Saturation_%28magnetic%29

http://www.allaboutcircuits.com/vol_1/chpt_14/4.html
http://www.coilgun.info/theorymath/saturation.htm
at least one of those specifically states that air core magnets do not saturate.

you can oppose gravity, but you cannot neutralize it. yes, you can levitate with magnets, but if gravity were not still in operation the item would fly off into space due to centrifugal force. if just levitating something is evidence of neutralizing gravity then you can do it by just using pressurized air to lift something... of course you could theorize that the military has figured out how to neutralize gravity because they use hovercraft, that would make a nice conspiracy theory.

I am anxious to look at the browsing hints you supplied in your other
posting . But for the moment I want to look at the word "neutralize"
which I refer to as generating a state of equilibrium. We are
obviously intending the same meaning or observation so now I have to
look up the dictionary to see what the problem is with the term
"neutralize"
Thank you

>you can oppose gravity, but you cannot neutralize it.

Let's compare the force of gravity of earth to the force of
electromagnetic interaction of electrons:

Take a balloon,
rub it against your hair,
put the balloon close to the ground,
pick up an ant with electromagnetic interaction,
Gravity loses.

If this were "anti-gravity" then patents would be used for wallpaper.
(Have I just revealed a secret? Are there any new antenna designs
appearing on WikiLeaks?)

> at least one of those specifically states that air core magnets do not
> saturate.

You are correct about the existance of the statement regarding
saturation of air but that is playing on words comparing the very
least of
return for power applied versus a ferrite enclosed in a pocket of air.
Now we have a situation that infers that it is when a ferrite attaines
saturation then excess flux is retained by air such that force has
made a transition from its previously linear form. But the fact is
that the electric field also drops such that regardless of the
increased size of the coil the flux containment of air is now dropping
from the maximum point attained and cannot exceed that point. Now you
can make the point that this is not truely a point of saturation
because of the increasing flux requirement for minimum retainment but
the real world shows that when the maximum point is reached, that
point cannot be retained.
Interesting subject., thanks for your interest
Regards
Art

Balan and term resistors can be purchased here
http://www.packetradio.com/catalog/index.php?main_page=index&cPath=45

Or you can build the term resistor and balum yourself
I used a carbon watercleaner cartridge to build my term resisor :-)

Hi ...

I am let to chime in, but I would really like to take part in the discussions.

Aurthur, I am a student of physics. The way I understand the situation is as follows:

There is no charge moving. In practice, nothing is moving. an EM (strictly E) field is created, into which power is distributed. So if you pump more power after some saturation, the medium will breakdown to provide an alternative mode of transport, i.e. direct conduction in this case

Therefore i would appreciate if you elaborate what you mean by trajectory of the charge.

s

Hi Sean
Re acceleration of charge.
First I have little training in physics so I am not pre programmed. I am an old retired mechanical engineer
Stating facts as I see them.

Adding time variant to a Gaussian field results in Maxwell equation for radiation establishing a particle as a carrier of charge. Solar particles are attracted to diamagnetic surfaces which are also used for radiators.
Only one resistance reflects energy supplied to a charge. the other resistance of skin depth is a loss.When a external magnetic field is removed from a radiator so is skin depth and current flows on the surface. For Maximum efficiency the particle must be raised for friction reasons and a displacement current does just that. Now a Faraday cage I see as a separation
of fields imposed on a particle,The magnetic portion stays on the outside of the shield and the electric field alignes itself on the inside
cancels leaving only AC current , a reverse of radiation transmission
For a solenoid we have all the above features, A Faraday shield around a radiator. The radiator is a Meander form and resistive or non frequency relevant. Now the radiator is energized for transmission B reaches saturation
energy transferred to H until the coil becomes diamagnetic. The displacement current raises resting particle neutralizing gravity and is in equilibrium.All energy applied to the particle is now equal to acceleration of charge for maximum efficiency such that the thrust and spin allows for straight line trajectory. All the above can be seen from superconductor reaction equivilency. The two vectors of thrust and helical spin applied to the particle are Newtons reaction to Earth's position in the Universe and reflected by the two vectors of a time variant current which is also the same as
a boundary break to release a particle from a Gaussian field during the Big Bang and the basic forces envisaged by Einstein for the Standard Model ala the twisted ladder of life itself.

Searn
It has taken me several years to convince some
of the transition from electrostatics of Gauss to the Mathematics of
Maxwell to establish particles instead of waves., Probably the cgs
units create confusion. I would have liked to start from the "double
slit" experiment which has created a monkey fist stuck in a jar. If
only people could step back from a stubborn position
it would be an easy transfer of thought from a double slit experiment
to one of a array of slot antennas to get things back on track. The
last few years has taught me that many see passing the amateur radio
exam as a passport equivalent into the society of physics and the
protector of printed books of the ARRL so I am clearly outnumbered
with respect to the resistance to change.

Sure!
I have dremmel-tooled open a used dried-out water filter cartridge from my fridge that contained a hollow carbon shaft about 10" long and 3" in diameter with a 3/4 inch hollow inside diameter. The end to end resistance was about 600ohms. The carbon shaft is a bit soft and crumbles under the pressure of tools. This was how I destroyed the first unit I played with in trying to make it 480ohms by trimming the ends.

Using another filter, I encapsulated the carbon shaft inside a sewer tube. (Denser PVC and hopfully more impervious to heat) I attached conductors to the ends using flat washers with springs and left vent holes in the PVC end caps when I attached them to push it all together. I did not attempt to trim the resistance by shaving the length. The modules finished resistance measured ~590ohms.

Since this WAS a used water filter, I ran some HV through it to heat it up a bit to see if it would vent gas or smoke. The resistance decreased a bit as it heated but returned to near 600ohms when it cooled. I kept the power to less then 100w using my bench HV power supply. After about 1 minute, the PVC started to feel warm but no smoke was seen though it did stink a bit.

The whole PVC module I made sweeps out flat from 1Mhz (bottom of my test gear) to ~40Mhz where I think my wiring started having some effects. I had to use springs on the ends to push the contact washers up against the carbon shaft and suspect I need to come up with something better here. Also, the pressure of the springs and end caps varied the resistance about 20 ohms.

I have run about 400w avg for several minutes into the load under voice and so-far the damn thing is still hanging on the T2FD antenna and loads just fine. In usage, the resistance varied about 50ohms upward in the

last several months of tracking it. I hope to remove the resistor shortly and inspect if there is any chemical reaction with the steel washers and the carbon rod ends. I need some better way to make this contact and also some way to increase the surface area of the contact to stabilize and perhaps reduce the resistance. I'm thinking copper pipe endcaps heated up and cooled over the ends either on the outer diameter or on the inside hollow part of the carbon shaft.

/****/
Another idea I just had is perhaps having someone with a ceramics oven paint on the endcaps with ceramic glaze. It would look like a giant ceramic resistor! But then again, I would guess that as the resistor heated up, it would crack. Never mind...
/****/

I now have another filter module to dissect. I hope to come up with a better way to mount contacts to the carbon shaft and some way to assure a nice airflow around and hopefully through it to allow for higher power.

In retrospect, with the amount of time and work I've put into this resistor project, I would have been better off purchasing the buxcomm resistors for $25. (I have one) But then again, I had fun playing with this too! If anything, ideally, I hope to come up with something that weighs half the weight of the buxcomm resistor so my T2FD antenna looks more graceful under the burden of the resistor. :-)

73!

A better way to attach it may be to electroplate Cu on the ends of it.
Did this with some battery cores one time. Think I used CuSO4 solution
as the electrolyte.

The water cleaner cartridge is activated charcoal with a small amount of organic binder. It is not graphite as graphite will not function to clean the water. Activated charcoal has an extremely large surface area which adsorbs contaminants. Depending on how it is produced, a gram of activated charcoal can have from 100 to 1000 square meters of surface area.

Your idea of a metallic ceramic glaze will not work as the glaze is a low temperature melting glass (usually a lead glass) with fine metallic particles in it. Once fired, the glass melts, but the metallic particles are still insulated from each other.

You can buy conductive copper, nickel, and silver based paints for repairing printed circuit boards. GC Electronics sells small bottles of silver print paint (Part No. 22-024 1 troy oz. Bottle) which has a surface resistivity of 0.1 ohms per square, and nickel print paint (Part No. 22-207 2 fl. oz. Bottle) which has a surface resistivity of 5 to 6 ohms per square. Be extremely careful when diluting these paints. Use only chemically pure solvents as any oil or other such material in the solvent will serve to insulate the particles from each other. GC Part No. 10-4102 Polystyrene

Q-dope thinner (toluene) might be suitable. I would suggest the nickel print paint as the silver print is quite expensive. Heed the warnings in the respective MSDS's for these products.

Another alternative is to have the ends of the activated charcoal rod electroplated. A thin copper flash film applied to each end, followed by a thicker conventional electroplate would give you contacts that could be soldered to. If there is someone in your area that does electroless nickel plating, this would also be suitable.

An entirely different approach would be to use a conductive liquid for the resistance. An old QST article in June, 1965, entitled "Aqueous Dummy Loads" by Alexander Marion, W2CUE (now a silent key, I believe), should give you some ideas.

5010. Rigid, unguyed dipole end supports?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-06 14:23:46 UTC
From: Bert Hyman <bert@iphouse.com>
Message-ID: <Xns9E4655692A4DBVeebleFetzer@216.250.188.140>
Source record: 6410

The size and layout of our city lot means that I can fit a 40 meter dipole in the back yard with one end supported at the peak of the roof, but with no way to guy a mast to hold up the other end. Power lines run directly along the property line in back, there electrical service line runs right across the roof of the detached garage and there are no trees back there.

I picked up a couple of [cheap] 10' steel mast sections at the local Radio Shack and attached the lower section to our fence with conduit clamps, but just the weight of the antenna under minimum tension causes the upper section to bow significantly.

I'd like to replace the far-end support with something that will stay erect under tension without guys. Getting higher than 20' would be nice too.

Can anybody offer practical suggestions to someone with essentially no mechanical skills, pointers to articles on the subject or commercial products?

While it may not be too inexpensive, you can use some Rohn 25G tower sections. There may be soe other inexpensive tower sections you can use. I was in a similar situation. I could support one end and the middle of an 80 meter dipole. I found some used tower for about $ 30 per 10 foot section. I was going to save it to put up a tower someday. I decided I could put two sectons together and also use one of the 10 foot sections of TV mast like you have. I think the TV mast woud fit over one of the legs. I also put a big eye bolt at the top of the mast with a rope through it so I could pull up the antenna wire. This was done before the tower was raised so there is no need to climb it. To climb it I would think you would want about a yard of cement in the ground, then you could go up to about 30 feet of tower. I just rested the tower on the ground and took a couple of radiator clamps and fastened it to the pipe that held up the corner of the chain link fence. I used it this was for about 3 years before I moved.

I set up an 80m dipole using three masts made of 20 foot long 2x4's from the lumberyard. I don't use any guy ropes, even on the end masts. I just made diagonal braces from shorter 2x4's -- about 6-8 feet each -- with two braces on each vertical mast.

The braces are attached to the mast with carriage bolts and one long lag screw for the brace that attaches to the narrow edge of the mast. The braces are arranged at 90 degree angles to each other and are dug into the ground about 1 to 2 feet deep (that's all I can dig in this yard before hitting hardpan). Each brace has a short "deadman" stick screwed on the bottom of it to keep it from pulling out of the dirt.

There is also a vertical brace dug into the dirt and rising about 3 feet above ground line. The actual mast is lapped onto the vertical brace with two carriage bolts. The purpose of the vertical brace is mostly to get the maximum rise out of the 20 foot mast. You could also just bury the end of the mast itself into the dirt.

It's been up for a year now and hasn't come down even in the wind storms and ice storms we have had. Be sure and orient the 2x4 mast so the "strong" direction is opposed to the weight of the antenna.

Electrodes from an carbon arc light or pencil leads can also be used for
a non precision resistor.

Carbon "suppressor" ignition wire

Copper sulfate in water makes a nice resistor, too. It's used a lot for
"energy dump" resistors in pulse power applications.

The power limiting thing on resistors like this is the packaging. If you
put it inside PVC pipe, then the thermal resistance of the PVC limits
how fast you can get the heat out (and the maximum temperature, too)

That sounds like something I've seen on utility poles, except that the guy doesn't connect at the bottom of the mast, but goes straight down from the strut, parallel to the mast, and is anchored in the ground. I probably have enough room on the other side of the fence for something like that.

BTW, I'm collecting and "analyzing" all these responses for next spring; the ground's already frozen and we have our first foot of snow cover for the winter.

From a theoretical standpoint, copper sulfate solutions should increase
their resistance with frequency more rapidly than the sodium and ammonium
chloride solutions used in the ARRL article. This is mainly due to ion
mobiity in solutions.

> The power limiting thing on resistors like this is the packaging. If
> you put it inside PVC pipe, then the thermal resistance of the PVC

Heat transfer was the primary reason for using transformer oil or mineral oil in the old Heath Cantenna. Without the oil, the Globar carborundum resistor would rapidly overheat. With the oil, the resistor could could dissipate 200 watts continuously. If you started with room temperature mineral oil, it could dissipate a kilowatt for about a minute before the oil got too hot and reached the flash point. Medicinal mineral oils have an open-cup flashpoint between 171 and 221 °C depending on the specific manufacturer, while that of technical grade oils is somewhat lower. Of course, Heath suggested removing power to the Cantenna when it reached 60 °C [the temperature at which the can is too hot to touch continuously]. At the time the HN-31 was produced, transformer oils generally contained polychlorinated biphenyl (PCB) additives which reduced their flammability. This is why Heath rated the Cantenna at 1 KW for ten minutes or less when it was filled to the proper level with transformer oil.

I have a Bird dummy load rated at 1 kW continuous. It has a larger
resistive element, still immersed in oil. However, the case is finned to
help dissipate the heat.

Jim is quite correct about the PVC pipe limiting the heat transfer. I
would suggest using power chip resistors. Digi-Key carries Bournes chip
resistors rated at 50 ohms and 100 watts for less than $8 each.

Copper sulfate is popular because it is compatible with copper
electrodes, too. Sodium chloride tends to corrode the electrodes.

There might also be some difference in solubility, which would affect
the range of resistances available.

http://home.earthlink.net/~jimlux/hv/rwater.htm has a discussion of
building water resistors for HV applications.

Hi Bert:
Let me tell you what I'm using for my dipole. I have a 40' tower about the middle of my lot. The dipole center is supported by the tower and the ends are supported by flagpoles. In the front yard its a real one piece spun aluminum flag pole for the "looks" and in the back the pole is a 21'long 1 5/8" steel pipe that is used for the top rail in industrial chain link fencing. Both poles are mounted as flagpoles are commonly done (look up erecting flagpoles on the web) with 2' of the pipe in the ground making it 19' out of the ground. The advantage of flagpole mounting is it's relatively easy to take down if maintenance is need. My dipole is heavy as it's a HB fan dipole and covers 160 through 30 meters. I though the pipe would bend too much so when I put it up I fastened a rope the back side of the top for a back guy. I never used it and when the time comes to work on it (paint maybe) I will remove it. Works well and looks good and not hard to put up as I did it with out any help.

John W3JXP

The fence top rail stuff is actually rigid enough to not only stand up
by itself, but to support a little side load? Any idea how much farther
up you could have gone without the thing starting to get floppy?

Sounds like something worth looking at.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

Amen on the thick-film chip resistors. I built a 200W dummy load using two 100 ohm 100W devices in parallel.

Yes, I had a friend who was in the Navy during WWII, he described how
they used buckets of salt(sea) water for dummy loads. The further you
put the electrode in the bucket the lower the resistance.

John, the weather is just now getting to where we can begin working on antennas. 4" snow on the ground and rain predicted. Perhaps tomorrow I can start working on tightening up the four corners of my 160 meter horizontal loop. Or finish tuning the 5BTV out in the pasture.

Have been thinking about a Beverage. Have mile or more of tiny shielded wire I got at Boeing Surplus years ago. It's about 1/16 inch diameter. Silver plated copper. Used in aircraft, somewhere. Figured I would tie inner conductor to shield. Use 1" pvc pipe about eight feet long for supports. Drive rebar into the ground as far as possible (18") and stick the PVC over it. Put the wire in a slot at the top. I can run the wire SW almost 600' before I hit the edge of the property. Then a 2 watt carbon resistor to ground. Need a transformer at the house end to match to coax.

Also need to get started on cleaning up and painting the tower. Haven't had time to get it up. Mayby have to wait for another 5 years!

There, is that enough about antennas?

Not the time of year to be working on antennas.
Also, we had a spike in traffic during the DTV
transition. It's all kinda tapered off.

5028. Balcony Antenna for Shortwave Listening

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-07 23:11:16 UTC
From: Sébastien MEDARD <titi@tut.com>
Message-ID: <4cfebf14$0$7537$426a74cc@news.free.fr>
Source record: 6428

Hello,

I am a complete newbie in SWL.

At fourth floor (last one) of a building, I get a balcony where I could put an antenna for ham and broadcast reception (SWL). Well the balcony is quite small, but quite comfortable too :)

Now, I get a poor wire from my flat to the ground (near the ground). It gives me some night reception for broadcast from 500 KHz to 1500 MHz (it is quite interesting, but quite limited too...). Except that, I get nothing. Frustrating.

I planned to build some loop antennas, but first of all, I wanted to focus on long wire antennas.

Please, give me your thoughts:

I am about to build a long wire antenna, but something quite different... Like hand-held receivers antennas, I want to wrap 100 meters of standard wire around on a 4cm (diameter) plastic tube (like a slinky antenna).

I get three different ways to do that:
- like the standard long wire, feeder on one side with a 9:1 balun
- like a dipole (feeder at the center)
- like a 1/4 wave (vertical one) with the steel fence for the ground and to hang up the plastic tube. The fence itself is grounded.

What do you think about this type of antenna?

What about the reception efficiency of each kind of solution for all bands between 500 KHz to 30 MHz?

Tell me if it is interesting to test that or I should not lose my time and begin building a loop antenna?

Thanks.

Sebastien.

In French :

Hello,

Ma situation est la suivante. Au 4ème et dernier étage d'un immeuble, je dispose d'un balcon sur lequel disposer une antenne pour recevoir les émission broadcast et les émissions radio-amateur en HF. Evidemment, c'est assez petit quoiqu'assez confortable.

Pour le moment, un vague fil pendouillait par le balcon, ce dernier m'offrant un peu de réception, de nuit entre 500 Hz et 1500 MHz (c'est pas inintéressant, mais c'est limité....). Sorti de ça, je n'ai rien. Fort sentiment de frustration.

J'ai en projet la réalisation d'une antenne loop, mais dans un premier temps, je voudrais me concentrer sur le long fil.

J'aurais voulu avoir votre avis.

Je suis sur le point de construire une antenne de réception de type long fil, mais modifiée... A l'image des antennes de réception des récepteurs portables, je pensais bobiner une bonne longueur de fil (une centaine de mètres) sur du tuyau PVC de diamètre 4cm (fil électrique de base, bobinage à spires jointives).

Trois possibilités s'offrent à moi :
- Alimentation par une extrémité, le long fil classique, mais bobiné
- Alimentation au milieu en doublet 1/2 ondes, évidemment toujours bobiné
- Alimentation en quart d'onde, verticale (encore bobiné), en utilisant la rambarde métallique comme terre (et comme support pour mon tube), la rambarde faisant la longueur de l'immeuble (la rambarde étant elle-même raccordée à la terre).

Que pensez-vous du principe ?

Et que pensez-vous du rendement de chacune des solutions en HF toutes bandes ?

Avec mes remerciements,

Sébastien.

Hi Sebastien,

Use an antenna tuner (same thing Amateurs use, but without the
meters).

You probably need this because of the Broadcast transmitters. Those
transmitters can force your radio to create an AGC voltage even when
you are not tuned to the Broadcast frequency. This AGC voltage causes
your radio to lose sensitivity.

To put it another way, suppose:
you have a strong Broadcast station nearby on 1 MHz;
you connect your radio to a long antenna for SWL;
you tune to the 31M band;
the Broadcast signal creates a very strong AGC;
you (naturally) do not hear the Broadcast signal;
you (un-naturally) do not hear many 31M band signals.

To solve this:
Add a tuner;
you adjust it for the 31M band;
it removes the Broadcast signal;
your AGC voltage is now based on 31M band signals;
your radio becomes very sensitive;
you hear more 31M band signals.

This will also work for weak Broadcast signals.

You cut corners :) I was thinking about adding a Tuner or maybe something that is called preselector/tuner...

But, before that I just wanted to know what would be a good antenna, or good antennas for where I live.

Thus, I was thinking about adapting the basics (long wire, dipole) to my situation. What do you think about shorting a long wire to a big self?

Would this self work better adapted on one side, like a dipole or a quarter of a wave?

By the way..... What would be a good antenna tuner for a SWL? Any advice for a brand? Any advice for a good DIY kit? :)

Thanks.

Sebastien.

Here's my suggestion. It's a combination pre-selector and amplifer:

http://rffun.com/catalog/preamps/2158.html

If you are handy with a soldering iron you can easily add a second receiver
output.

>But, before that I just wanted to know what would be a good antenna, or
>good antennas for where I live.

Hi Sebastien,

The best is the one that will be as high as possible. Length should
be 5 to 10 meters. Orientation should be broadside to the stations
you want to listen to. You should have a choke (W2DU style BalUn)
connected at the feedpoint. One example shown at:
http://www.n0ss.net/qrp_1-1_w2du_coaxial_balun.pdf

You should think of more than one antenna (maybe one vertical, one
horizontal).

Paying attention to your ground is important, but if you live upstairs
in an apartment, then think dipole (even if one side is vertical -
where the horizontal wire would be called a "long-wire").

>By the way..... What would be a good antenna tuner for a SWL? Any advice
>for a brand? Any advice for a good DIY kit? :)

The price you could pay is not a predictor of performance. Look at
the schematic on the last page of:
http://www.mfjenterprises.com/man/pdf/MFJ-902.pdf
It can be built from parts for less than $100. It basically
represents the most flexible design, but there are other useful
designs. Even there, with a good switching design you could use the
same components to build them too. (I am thinking of PI
configuration, L, and so on).

Old AM (tube) radio parts are perfect for building your own tuner.

Great post! I am always interested in the projects of others...and the
results, good or bad. I quit thinking about a Beverage due to
unwelcome horse traffic. For some reason when people get a horse they
think that it comes with a license to treat their neighbors property
as open range! I don't mind the traffic, it is the risk of the horse
getting tangled and injured in my ever changing antenna projects. And
then there is the matter of the ever present Road Apples that my dog
finds so attractive...

There is never "enough" information and experience reports on antenna
experimenting!

An Interesting incident this past week:
A few days ago I was chatting with a friend on the telephone and tuning through the 20m PSK-31 when I heard a 3 land call with a CQ. Since most PSK contacts are a matter of a few keystrokes I answered him. I needed to verify the SGC-237 tuner was working properly on the 30 foot vertical anyway. From that point I just had to share the QSO with my buddy Bill on the telephone. It turned out that the contact was Maritime Mobile off the coast of Angola Africa where he is the Captain of a sea-going tug (220 Feet!) that re supplies oil drilling platforms!

I keep hearing that it takes a beam antenna way up in the air and lots of power to work DX. I was running 30 watts PSK into an end fed half wave vertical that is a ground level.

I keep hearing that the problem with verticals is that they radiate equally poorly in all directions...

Those Hams that complain that they cannot work HF because of antenna restrictions could do the same with a flag pole antenna.

This is one of the appeals of PSK31..

You don't need much radiated power to work the world. The bandwidth
really is 31 Hz, after all.

I've got 236 worked and 223 confirmed, running 100 watts into a
vertical.

> I keep hearing that the problem with verticals is that they radiate

> the displacement current raises resting particle neutralizing gravity
and
> is in equilibrium.

Ok every one ..

the gausian field does result in maxwells equation. thats right.
solar particles are attracted to diamagnetic surfaces ... I dont
understand this. they have magnetic field lines frozen to them, if the
temperature is below some critical value, and are attracked bz other
magnetic field lines. thats a big story from MHD

some resistance leads to energy loss .. probably energy is being
converted to heat, not loss.

Current flows to a radiator skin --- farady said it should be so --
charge must move to outer surface

for maximum efficiency particles must be raised due to friction
reasons.. most likely not.
they dont feel friction, but the do encounter collisions, and the emf is
supplied to overcome the unwanted energy conversion during collisions.
They probably do not raise at surface because of efficiency issues, most
likely, as much as I know, they leave surface because ot surface is full
of electrons supplied from the electrode by the emf.

and the raising probably do not neutralize gravity, the field is putting
a larger force than gravity on those particles.

I can imagine gravity being turned off, but for that i would expect the
force to arise from a mass field, or something which has no component
along gravity. Art, how do you be sure that this force is "turning off"
or neutralizing gravity, and not just "working against gravity"

regards
s

Heat is not loss if heat is your objective. This is a curious
objective in light of the topics discussed here.

>for maximum efficiency particles must be raised due to friction
>reasons.. most likely not.

Must be...likely not. This is a curious self-annulment of a
statement. Basically it erases itself as a concept. One has to
wonder why bandwidth was expended in its expression.

>they dont feel friction, but the do encounter collisions,

Particles "feel?" Well, if we were to descend to anthropomorphizing
inanimate objects, then what would friction feel like but one bumping
into another? Again, a curious self-annulling statement and more
wasted bandwidth.

>and the emf is
>supplied to overcome the unwanted energy conversion during collisions.

"Unwanted?" Putting that "feeling" (now psychological) aside, we now
have spontaneous energy (emf) springing out of the void? A cure for
entropy has been discovered.

>They probably do not raise at surface because of efficiency issues,

Efficiency has now become an actor ("because of")?

>most
>likely, as much as I know, they leave surface because ot surface is full
>of electrons supplied from the electrode by the emf.

Ah, the source of emf! Well, that being said (and I am not sure that
saying it is enough), how much emf is required to accomplish this feat
of leaving the surface?

>and the raising probably do not neutralize gravity, the field is putting
>a larger force than gravity on those particles.
>
>I can imagine gravity being turned off, but for that i would expect the

Asking for explanations is not nearly as useful, or even productive, as asking for solutions. As with my question above about "How much emf?", the solution to that is a number with units of measure. If the number is unsuitable for a solution, no amount of explanation will replace that. If no number is offered, there is no explanation.

Words may be written, but they amount to fantasy only. Only the patent office will publish fantasy that conventional publishing would discard.

Temperature is not involved. They form a skin
or boundary with hoop stress

>
> some resistance leads to energy loss .. probably energy is being
> converted to heat, not loss.
No energy conversion, they are at rest.

>
> Current flows to a radiator skin --- farady said it should be so --

Excellent
>
> for maximum efficiency particles must be raised due to friction
> reasons.. most likely not.
> they dont feel friction,
They must be placed in equilibrium otherwise you have a peeling action
that is a loss.
Now we have a single action and a equal reaction in place with no
losses.

but the do encounter collisions, and the emf is
> supplied to overcome the unwanted energy conversion during collisions.
Apparently particles in flight have a repelling force between them.
Either way the two vectors of current and displacement is applied
to the particle.
Now this particle does not take off with a parabolic curve and fall to
the ground because of gravity. The particle travels in a straight
line.
The two vectors applied to the particle are equal and opposite to

Gravity and the rotation of the Earth

> They probably do not raise at surface because of efficiency issues, most
> likely, as much as I know, they leave surface because ot surface is full
> of electrons supplied from the electrode by the emf.
The electrons at rest are free electrons and are not part of the
substance or mass upon which they rest. An example is the skin upon
water which itself is a diamagnetic material. Place a magnet near the
skin and it will repel or bend the skin surface.
>
> and the raising probably do not neutralize gravity, the field is putting.
The problem here is the word neutralize. Gravity enforces itself with
a vector that provides certain phenomina such as dragging a particle
to the ground. If one renders that vector neutral by an equal and
opposite force
then our little particle carrying a charge is not affect by gravity
and unless impacted by another vector or a magnetic field it will
continue to travel in a straight line.

> a larger force than gravity on those particles.
>

You do not turn Gravity off! You can have a vector working against
gravity and in a loosing battle no less, but until that vector is
equal and opposite to gravity the effects of gravity cannot be said to
be neutralized. Remember, we are only relating to the vectors implied
upon the particle alone according to boundary rules.and the
"resultant" vector remains a straight line.

boy... what is happening here - i feel lost

firstly, Art, temperature IS involved, when we are talking about solar wind plasmas

second, richard, i guess my sentencing style is confusing
"some resistance leads to energy loss .. " <-- this is copied from art's previous message (if you follow the messages, you would notice the copying)

"probably energy is being converted to heat, not loss." <-- this is what i commented

probably now you see why some other sentences appear self contradicting because the first part is art's message, second part is what i write

and sorry for writing "feel", english is not my mother language, but i believe you understood what i wanted to express

.....

Art, can you please contact me to my email address directly, because i feel people dont like us discussing something.

you can see my email address in the message, can you please also make some diagrams etc.. ?

thank you

You are correct, the group does not like this sort of thing being
discussed and so will attack you.But to go private is to run away from
them.
None of them have offered alternative solutions
or even addressed the problem so they present no harm to any
discussion as it is all beyond their ken
Cheers and beers

That is why I said separating the report from the reporter (who is the
author of what is being written?) is a strain.

>"some resistance leads to energy loss .. " <-- this is copied from art's
>previous message (if you follow the messages, you would notice the
>copying)

I have long since abandoned reading Art. If the sense of my response
to your post is any indicator, then you can well imagine the waste of
time in that pursuit.

Let's just look at this isolated, attributed quote you have re-framed.
Look between the quotes you offer - not much said there that isn't
already obvious. However, valid quotes in isolation are one thing,
but stringing them together does not bring any authenticity to a
"theory."

In other words, cut and paste phrases is not a logical argument.

>"probably energy is being converted to heat, not loss." <-- this is what
>i commented

Then there is a problem that is attributable to you. If you want
heat, then that is not loss in the conventional sense. You have not
clarified your intent.

>probably now you see why some other sentences appear self contradicting
>because the first part is art's message, second part is what i write

You need to employ the conventions of newsgroup etiquette, then. The
fashion of my interlacing your comments and mine clearly distinguish
who is the author. This is done by the distinct characters that are
inserted by a news-reader. This is an automatic feature.

>and sorry for writing "feel", english is not my mother language, but i
>believe you understood what i wanted to express

But I could not distinguish you from Art to be able "to give you the
benefit of the doubt."

>Art, can you please contact me to my email address directly, because i
>feel people dont like us discussing something.

Why don't you email him directly?

Sean, I agree, stand your ground.There are a few good people in this group it is just that some post more than others without content. If their posts have no content for debate then they are of no interest to you. You personally had no trouble with respect to particles while others are still struggling with it So your expectations of them to provide info is just misplaced. It is my belief that they reject Maxwells addition with respect to displacement current as they do not understand and also deny simple levitation.
As a radio ham you knew before hand as you that skip represented straight line trajectory
and you easily recognized the tran as well as the
transition from static to dynamic. I am sure you also know that only units used by Mawell represent the path
to maximum efficiency in radiation as well as
the ratio of capacitance to inductance must be
unity. At the same time you must also be aware that once the particle is raised it is in equilibrium the same as the maglev train removes friction from the equation.
For efficiency in radiation you are only interested in radiation resistance and once applied current rises to the surface of a conductor the particle has nothing to resist the applied current accelerating it. What is important in all these transitions is the term diamagnetic which REJECTS a magnetic field whereas a magnet attracts. Forsuperconductors
a similar thing happens in that the conductor becomes diamagnetic and rejects a magnetic field, it is no longer intrinsically carrying a current. The idea to explain straight line trajectory of a charge was the notion that no mass was involved for gravity to act upon.
Not only does Gauss point to the error in this thinking but 20th century experiments show that mass is present. But all still resist change
but have nothing, but nothing, and thus keep their hands clenched inside the cookie jar.
Now look at the Yagi antenna, it is not in equilibrium and it actively uses magnetism as its driving force. It certainly does a good job in producing productive gain in a particular direction but for efficiency it is miserable when compared to a dish radiator. Why? because it deals with two separate resistances where Maxwell implies only one. Efficiency means that all work done is solely to produce a said requirement without unrequired and incidental loss.
Now think about the reciprocal of transmission
with the Faraday shield in mind. It is the only thing that separates

electrical and magnetic charge/fields to leave just current., Now put a radiator inside such that the fields produced
changes the enclosure to a diamagnetic structure. I will leave you to figure out the rest with respect to what flows on the surface and not within the shield just like a superconductor.
Start off with a radiator where a field can increase no more such that it moves to increase another field to generate an exceedingly strong field while reducing the field from which it was transferred. Now watch for the hyena howls from those who resist change and see what they have to offer.
Regards
Art KB9MZ....xg

Sean, the poster is qualified to speak into a microphone as he has a
ham licence. However he freely admits to not graduating from high
school, so please judge his comments on his background. He is not the
only one in this group that has ham licence and feels qualified
in physics to a University level.
Anybody can post an opinion on this newsgroup
even tho the title has a suggestion of some antenna expertise. On the
other side oif the coin there are a few qualified and degreed with
respect to antennas but refuse to get involved
verbally with spammers on the side lines. We had a guy with a
doctorate from MIT who came aboard to explain Gauss contribution with
respect to amalgamating static with dynamic which you noted equaled
Maxwell's equation for radiation, but he left after they trashed his
mathematical input. Most still think that Gaussian input to Maxwells
laws only with respect to magnetics and nothing else despite being
shown the mathematics of the addition of a time variant to a Gaussian
boundary. Only a few understand the importance of equilibrium no less
or what it means, even tho it has been explained to them more than
once.
Everybody is mentioned in the archives with copies of their past
postings. You should get the message after viewing some of those, most
of which is just spam with zero content.
Stand fast
Art

Well you do admit to no high school graduation
and appear to be proud of it so it is a bit silly for you to throw
stones being such an easy target. Now if you were willing to learn and
debate we all could judge what you have to offer. I do agree that you
had a lot of experience with different antennas during your CB
days.Your interpretation of your experiments
however may vary from others. I f you do have some knoweledge that is
pertinent to my comments or overthrow them your standing within the
group may well rise but you appear to have nothing to share other than
spam.

So what is the reason you inserted yourself into this thread? What is
it that you wanted to offer to this thread? Do you have a problem with
the levitation of neutrinos that you just can't let go?Just pull out a
point stated in this thread and supply a reasoned technical approach
as to why it couldn't possibly be so. Perhaps you can start with the
Gaussian contribution with respect to particles instead of waves which
got you started way back when.
Your choice and chance to share your technical expertise with respect
to radiation and where you have a quarrel with what I present or
propose. So Sean as you can see there is considerable opposition to
talk in technical terms about radiation where SWR discussions
is considered to be the cusp of ham radio.

In the Navy, the shipyards all have a device called a Load Bank. It's
a
large metal tank on an insulated vehicle. The tank is filled up with
salt water and electrodes lowered into it to test the output of the
ship's
generators. Any chance that it has ham applications? I intend to try
it
first with an antenna analyzer and then, if it looks promising, my rig.

Yes they did the same with transmitters, often all you need was a
metal mop bucket and a piece of copper pipe.

I came by some glass rope (believe it was used for making fireproof
curtains) I saturated it in resin to make some fiberglass rods. I
would think other types of rope impregnated with resin may work, Ive
seen burlap successfully used with resin so I am thinking hemp rope
may work.

I lost interest in that subject pretty quick the last time around. It
seemed to quickly degenerate into what my Dad referred to as a "Peeing
Contest" which he further explained as a vicious argument short on
facts, long on anger and unlikely to have a conclusion or any
redeeming value.

My current view of the subject "Antennas" is that their are two
relevant components. The first is antenna geometry, the second is
matching it to the load.

Geometry determines the gain and the patterns across the spectrum.
Matching relates to minimizing losses.

I reserve the option of changing my mind but at least for the moment I
consider these as Axioms, that is: accepted principles.

Next I deduce that a "Perfect Antenna" is one that meets or exceeds
one's current needs.

It then follows that the "Best Antenna" is best one that can be
implemented within the projects available resources.

Anyone care to debate further?

> schematic on the last page of:
> http://www.mfjenterprises.com/man/pdf/MFJ-902.pdf

Seems not so simple for me.

I see two things on the schematic :

- 2 variable capcitor and an inductance on the center
- A balun for balanced line (ie dipole????)

As I already get a balun for dipole could you confirm that I just need the
center part of the schematic?

If the answer is yes, if I understand the schematic well, both of
variable capacitors are put one after the other inserted into the line.
The big question is how to make the variable inductance? Some wire wired
on a ferrite rod? (L ---------- A????) with a selector? Are the number
of half-loops means the number of turns?

> Even there, with a good
> switching design you could use the same components to build them too.

A water load bank is good for hundreds of KW at 60hz.

For use with a pair of 6146's we used to wire a lamp to a coax
connector. We had a load as well as visual indication of the relative
power output.

>The big question is how to make the variable inductance? Some wire wired
>on a ferrite rod? (L ---------- A????) with a selector? Are the number
>of half-loops means the number of turns?

Making the coil is easy. It is just bare wire. You connect leads
between various turns in the coil and a switch. A three to five
position switch will work. You can even wind separate coils and put
them on the switch so they add up in series as you turn the switch.

>> Even there, with a good
>> switching design you could use the same components to build them too.
>> (I am thinking of PI configuration, L, and so on).
>
>What is the influence of these different configurations?

Some antennas (I am speaking of their wavelength, not style like
horizontal, vertical, end-fed, or other) are easier to tune with these

other styles, but the style offered in the link is fairly general purpose.

>> Old AM (tube) radio parts are perfect for building your own tuner.
>
>It seems I need to find some :)

It may not be easy, but if you can find the right shop, you will find many. Tell the shop owner you want this for experimentation and you might get something that isn't in the shop display. The only thing you really need is the variable capacitor from two radios. This technology was very common and found in nearly every home in the 1950s and 60s, but now would be rare unless you find that shop.

>Thank you for your patience,

Feel free to ask more questions when it comes time to put this together.

Sean, let us review the initial question again but this time with
respect to the Faraday shield.
You may have seen a yagi antenna inside a circle or boundary to
explain a mathematical point. Well boundary rules state internally
must be in a state of equilibrium and a yagi antenna
is clearly not in equilibrium. Now a air solenoid
can be considered in a state of equilibrium which is resistive because
it is a meander form.
Its strength can be determined by K n sq/length
so we only need the solenoid to be the width of two wire where a
closed circuit is formed which is a requirement of equilibrium.If this
solenoid/
pancake antenna is placed inside a Faraday cage it can radiate a
signal if an opening in the cage is supplied. To receive the Faraday
shield can revert to a time varying current because both the
electrical and magnetic field which are the constituent part of the
current can only travel on the surface of the cage i.e. one field on
the inside and the other on the inside so they each cancel leaving
only the applied current in its singular form. One can argue about the
presence of skin depth but it is really of no concern here.
Now let us consider transmit. The pancake when energized will generate
a non frequency dependent radiating field which means it has a
bandwidth that can cover all amateur bands with a constant impedance
of 50 ohms as long as enough wire is used. It does this when the cage
being diamagnetic repels the magnetic field generated by the solenoid
which one can declared as non contributrary to RF generation.
This way we have isolated radiation generating force from non
productive forces such as element resistance both in transmit and
recieve
thus proving the reciprical effect.
When the above is applied to Nec programs in the form of a helix in a
closed circuit form it shows that if enough wire is present you can
get a very broard band where the gain increases to the high 20s dbi as
the magnetic field is rejected by the Faraday shield and where the
reactance deviations are so small that the arrangement can be

considered non frequency relevent. Key points in this discussion is equilibrium ala closed circuit that is resistive and the presence of a diamagnetic field that does not get swamped by a magnetic field that removes skin effect interfering with the movement of current to the outside of the confines of a element.
Now to make one of these radiaters one can use computer conductor tape strips stapled together and wound in between two flat plywood boards to a minimum of 2 ft dia and feed at the center. When removing the board spray a skin of foam over the pancake so that it can be easily handles. Tho the tape are electrically connected the current flow will still be the same as a contiuous wire or radiater. The pancake can be placed directly on the ground inside of a
bowl made of wire mesh where the outside of the bowl is directly grounded close by to syphon off noise.
Sorry about not using a spell checker to fend off the hyeanas.
Cheers and beers
Art

There was a man who did not graduate high school that many considered a fool and a kook. And to prove it, well maybe to prove it, he named his daughter Shanda. That's a bit odd maybe, but his last name was Lear. So he made a joke. Whether poor or not I won't judge. Obviously different than the pack, though.

So this non-high-school-graduate that had probably never even taken physics or chemistry decided to be an engineer. He read a lot, thought a lot, worked a lot, and designed something others said was not feasible - a small, inexpensive and reliable jet aircraft. The Lear Jet.

Putting people down because of their lack of a high school degree when they are obviously intelligent as well as quite thoroughly self educated brands YOU as unintelligent, not them.

Bill Lear attended school until the eighth grade when he dropped out
and joined the Navy as a WWI radio operator. That is the extent of his
formal education.

Besides the jet, he invented the first practical car radio, the patents to
which he sold to what became Motorola.

He developed radio direction finders, autopilots, automatic landing systems,
and avionics for general aviation aircraft.

He came up with the 8-track stereo originally to provide music systems for
his business jets.

The Canadair CL-600 Challenger bussiness jet is a Bill Lear design.

The Hannibal Regional Airport, William P. Lear Field was named in his honor.

Not bad for a high school drop out from Missouri.

I built a wattmeter of sorts around a circuit like that. After tuning
up the transmitter to light bulb dummy load I would measure the

resistnace of a photo resistor exposed to the light then see how much 60Hz AC voltage and current took to light the lamps to the same brillance.

if you were really good you could estimate the power from the brightness
in real time. it did take a lot of practice.

To
Jim,Tom, Sux etc
Why are you using different names addreses etc
on the same thread, All of which are talking to each other and using
the same computer to provide the thoughts of you, yourself and other
peoples names in a effort to show a unity of thought. Looking up past
posts of all these people show that a lot of people are using your
computer and talking to each other on the same subject, like talking
to the choir. All of your split personalities are easily reckognizable
when you use them to put down different people on the net.
Stop trying to hide your identity as your character always gives you
away. A fool is a fool which always stays a fool which is his
character that he can't shake. Which one of your split personalities
are you confering with on the subject of antennas

Hi Jimmie,

An excellent example of the concept of a transfer standard. This
method is one of the oldest and most robust methods of accurate
measurement. It removes a lot of variables (by, ironically, not
changing them) that would be exceedingly difficult to determine their
impact upon an accurate measurement.

I was reading about an Off-Center Fed Dipole (OCFD) antenna.

The following statement was made:

"An effective balun can be made by coiling up coax providing it is
self-resonate at or very near the operation frequency"

In the above statement, what does "self resonate" mean?

in that context it means that the coil of coax has distributed capacitance and inductance that at some frequency presents a parallel resonant circuit which makes a high impedance for currents on the shield of the coax. you can see the effects in the table on my web site (http://www.k1ttt.net/technote/airbalun.html) where there are peaks in the impedance of the air core 'baluns'... it is actually more correct to call them chokes than baluns since they really just try to choke off the current on the shield of the coax at the feed point.

Hello Sébastien,

For reception matching is not of primary interest. Good impedance
match may even overload your receiver.

The trick is to get sufficient signal (and nevertheless noise), so
that the antenna noise just exceeds your receiver noise. Further
investment in getting more signal output will not help your, it may
result in worse reception because of overloading electronic circuits
in your receiver.

If your balcony has a metal fence (that may be connected to rebar also), you can use this as a ground provision for a wire antenna of about 5… 10m.

Connect the wire to the center conductor of a coaxial cable. Connect the braid directly to the metal (without wire in between) of the railing, fence, etc. Feed the coaxial cable through the wall and connect it to your receiver's external antenna input. You must connect both center conductor and braid as (probably) shown in the user's manual. You may add ferrites around the coaxial cable to suppress indoor generated man made noise.

Maximize the distance between the building and the wire (so don't let it hang vertically down close to the building).

Adding a 9:1 transformer (outside, directly below the antenna) will increase antenna output at the lower bands. This does not automatically mean that your S/N ratio increases also.

Portable receivers may experience overload. A preselector may help. www.tetech.nl/divers/SimplePreselector2.jpg shows an (old) example. This one tunes from 3.3 to 26 MHz. By changing the crocodile clips, you can perform some matching to get more output from the antenna, and change the bandwidth of the preselection. Right side of the inductors is grounded to the copper, left side goes to the tuning capacitor. The switch adds the left half of the capacitor and 200 pF fixed capacitance for the lower bands. The shadow up-left is from the ferrite common mode choke (not shown on the image).

For the lower bands (AM broadcast) a loop may have advantage. The directivity of a (portable) loop you can use to enhance or suppress stations and/or noise. Small loops need to be tuned (with some matching also) to get sufficient output. Several portable SW receivers do not have an external antenna input for the 500..1600 kHz range (it always uses the internal ferrite stick antenna).

Figure 2(a) in http://www.compliance-club.com/archive/old_archive/030718.htm shows the construction of a loop out of coaxial cable. These types of loops have built-in balanced to coaxial transition. A square or circle of about 1m (diameter) is a good start for the AM BC band.

Be careful with (expensive) loop antennas. If you can't get reception with a simple well-constructed (tuned) loop because of local interference (noise), the most expensive loop will not change that.

Best regards,

Wim

Art, You have just mentioned a constraint on antennas that I was not aware of. Specifically "the ratio of capacitance to inductance must be unity".

This is new to me. Please tell me how I go about making capacitance and inductance equal so their ratio can be unity. How do you get the Farads and Henries to cancel out, leaving a dimensionless number.

Can you give me some real world examples?

joe

I will be happy to do so
Root L/C = 1

This means that L/C both of which are loss contributors are removed
from any formulae

Some balance needs to be returned to this (pun intended). The
expression BalUn is first and foremost found in what this word means
in full: Balance/Unbalanced and THAT is the principle transformation.
Turns ratio may come, but that is variable (2:1, 4:1, 6:1...) to a
design that must first meet the requirement of isolating one side that
is balanced from the other side that is unbalanced.

This is achieved in choking common mode currents - hence the BalUn
must effectively present choking action to meet this principle
transformation.

Windows has nothing to do with it; the problem is all Norton (or rather
Semantec).

Hi Ian,

A very good suggestion which immediately led me to:
http://www.phy6.org/outreach/edu/greaspot.htm

A variation of this that I calibrated in the lab is an Optical
Pyrometer:
http://www.pyrometer.com/Pyro_Optical.html

Comparison measurements can be very accurate iff what you are
comparing to (aka standard) is known to sufficient accuracy. Both
references provide more than enough to inform the reader with the
essential details.

Slightly more elaborate methods of measuring RF power fall into the
Calorimetric method (actual heat). Hewlett Packard made the ultimate
heat transfer standard - the HP 434A power meter DC to 12GHz!

neither L nor C contributes any loss in any kind of circuit analysis i
have ever seen.... its always the R that converts the electrical
energy to heat to remove it from doing something useful besides
heating the room.

> Richard Clark, KB7QHC

here comes the troll statement...

currents are always balanced and there is no transformation. the
currents in a coax are already balanced, on the inside. the action of
the choke is to prevent current from flowing on the outside of the
shield back to the inside at the antenna feed point. this forces the
return path to be the other half of the antenna if all works
properly.

let the balun wars commence!

>Lee KA0FPJ

It means take the coax feeding your OCF dipole and, at the end where
it attaches to the OCF balun, wind it into a coil about 6 inches in
diameter, 8 turns, tape it together so it doesn't uncoil and run the
rest of the coax to the rig.

Check out this diagram -- the guy calls his a "choke balun" -- 6 turns
of coax, 100 mm diamter turns.
http://www.vk3eg.org/technical/xlwindom/xlwindomhtm.htm

This balun is designed for use with and OCF dipole -- it has a
built-in 1:1 balun -- no need for a coax balun (coax choe) as it's
built into the balun.
http://www.balundesigns.com/servlet/the-75/OCF-balun-4-cln-1/Detail

Here's one guy's decription of how he built an OCF dipole using the
above balun:
http://w4hh.org/station%20antennas.htm

This guy uses 6-7 turns of coax, 6 inch diameter, as a coax
balun/choke.

I think HP made a number of DC substitution/transfer sorts of power meters
The 434 was unique in using flowing oil and it could directly measure
watts, without needing attenuators (which have their own calibration
issues).

Didn't the 432 used the idea of DC power substituting for RF power to
bring the sum to a fixed temperature? The difference between the 432
and the 434 is that the thing measuring the temperature is also the RF
load in the 432. The 434 just uses the RF as a heater, and relies on
the DC powered heater and RF powered heater being matched.

A NIST Type IV power meter (like those from Arbiter) definitely does DC
power substitution, and uses the HP/Agilent thermistor heads.

Once you get away from "replacement heat" sorts of schemes, you'd be
into the classic calorimeter.. measure the temperature change over time,
and then turn that into energy. You'd calibrate it by putting DC on the
same sensor, essentially measuring the thermal capacity.

The thermocouple heads (8481A, 8482A for instance) work pretty much the same way as the thermistor mounts.. measuring the heat dissipated by the RF power coming in. They're not a substitution measurement though.. The actual sensor changes voltage in response to temperature (with a clever compensation scheme so that overall temperature doesn't affect it)

But these are all basically thermal sensors (as opposed to, say, RF voltmeters, like a diode detector as in a 8481D or 8484A head) and they dissipate the RF power being measured.

Hi Jim,

I worked with a world of different methods of measuring RF power.
Thermistors, Thermocouples (the 8481A, 8482 you identify - refer to HP
Application Note 64-1, "Fundamentals of RF and Microwave Power
Measurements"), and the older technologies of Thermopile, Wollaston
wire, Bolometers (which encompass the same things as those already
mentioned), and Barreters (a variation upon, or exactly the same as
the Wollaston wire - I've seen 10mA fuses used for the same purpose),
diodes certainly (generally for peak power). I have had the occasion
to burn out more than a couple of these.

Those in a bridge configurations (many in fact as the 434 is an
example) are temperature tracking. An excellent description can be
found on page 14 of:
http://www.hpmemory.org/an/pdf/an_64-1a.pdf
for a thermistor bridge that compensates for ambient heat.

"The fundamental premise in using a thermistor for power measurements
is that the RF power absorbed by the thermistor has the same heating
effect on the thermistor as the DC power." This from the HP432A which
has a dual thermistor, dual bridge design.

Pages 18 through 20 describe how heats are separated in a thermocouple
bridge to compensate for ambient. From page 26 is discussion of
diodes.

As for accuracies: "All thermocouple and diode power sensors require a
power reference to absolute power, traceable to the manufacturer or
national standards."

A good remainder of the application note goes into the issues of
accurate determination. Pages 51 and 60 each has a table of all the
various sources of error (rarely considered outside of the Metrology
Lab, but ever present nonetheless). This was standard consideration
and the examples the author offers yields roughly 5% accurate
measurements from the best of instrumentation - an accuracy figure
that I frequently read here as commonly available from the Bird RF

meter (and I have the experience to the matter having calibrated these meters to know that is a fantasy of the first order).

i got a desk lamp from ebay like the one in the image link below. the bulb is held up by two adjustable telescopic rods, exactly the same type as you would find on the aerial of a FM radio. they are metal.

i saw the double insulated symbol on the bottom, which go me thinking. how did they get the wiring through these rods double insulated, they are pretty thin. then i examined the rods. they had joints in them. they werent even hollow! there was no wiring. they were the conductors.

a quick check with the meter gave 20V AC. thats how it was designed to light the bulb .

my question is can you have the double insulated symbol on a product with exposed 20V AC conductors?

Art,
That does not address the question at all.

How do the Henries in L and the Farads in C cancel to give a dimensionless
number?

A real world example would have numbers and a description the one could
duplicate to better understand what you are syaing.

joe

Very easy, the 20V is supplied from a transformer, (which must meet
the primary/secondary isolation standards).

Jeff

If you want one frequency, then it would imply one band.

If you want multiband, then you need to give us the other frequencies.

Think about it Joe
If you had an equation for efficiency it would be dimensionless.
Typically you would have a portion in that equation that depicts

perfection
and also a portion depicting deviation from perfection.So the second portion points to what creates losses and the first part points to perfection. Now look at root L/C which points to the constitution of that which creates losses.
Now ideally we would like this portion to be 1
which states zero losses, an ideal situation.
Thus we can say the losses involved equals
root L/C which must equal "1" Logic therefore tells you that both L and C are loss leaders whether they be lumped or distributed and therefore not part of the vectors that create
acceleration of charge. Remember for legitimacy all formulae must equal zero for equilibrium and therefore resolves into zero units. Now if you are unaware where root L/C
appears in the study of radiation this is a good time to hit the books to fill that gap.
Best regards
Art Unwin KB9MZ xg

What has been proved so far with this theory?
Particles and not waves
Magnetic fiels removal removes skin depth
Reprosity
The importance of diamagnetics
Vectors of currents, time varying and displacement are the equal and opposite of
gravity and rotation
L and C are loss leaders
Particles/ free electrons, are not the constituent
of the radiating element.
The Standard Forces are resolved by just the two vectors only created by the Big Bang or the
fracture of the original boundary depicted by Newtons law.
And it goes on but hams deny change.

Silly
Impedance consists of resistance Ra and reactance jxx. You can remove
resistance Ra from an element while the reactance constituent can
still remain.
Thus the impedance remains real.
Don't give up your job just yet!

A superior alternative solution from the 1940s (edited to length):

Work has been proceeding in order to bring perfection to the
crudely conceived idea that would not only supply inverse reactive
current for use in unilateral phase detractors, but would also be
capable of automatically synchronizing cardinal grammeters.

The main winding is of the normal lotus-o-delta type placed in
panendermic semi-boloid slots in the stator, every seventh conductor
being connected by a nonreversible trem'e pipe to the differential
girdlespring on the 'up' end of the grammeters.

Forty-one manestically spaced grouting brushes were arranged to
feed into the rotor slipstream a mixture of
high S-value phenylhydrobenzamine
and
5% reminative tetryliodohexamine.

Both of these liquids have specific pericosities given by
P = 2.5(C ï¿½ n^6) - 7
where
n is the diathetical evolute of retrograde temperature phase
disposition
and
C is Cholmondeley's annular grillage coefficient.

Initially, n was measured with the aid of a metapolar refractive
pilfrometer ... but up to the present date nothing has been found to
equal the transcendental hopper dadoscope. ... It has been
successfully used for operating nofer trunnions. In addition, whenever
a barescent skor motion is required, it may be employed in conjunction
with a drawn reciprocating dingle arm to reduce sinusoidal
depleneration.

lets see, you remove the resistance which is the 'real' part of the impedance, which gives you the imaginary reactance part as noted by the 'j' above, and you think its real... probably just as real as your pancake antenna in its faraday cage. you never have explained how my ferromagnetic antenna works without your magical diamagnetic levitating neutrinos.

Silly
Radiation is a vector product of two vectors, gravity and rotation.
The resultant vector cannot be at the same angle as the constituent
vectors there it must be tipped.

I found a PI network tuner shematic.

Many thanks for the first steps help!

Sébastien.

keep going art... is it tipped at the north pole? how about at the
equator? and does it tip clockwise or counterclockwise in the
southern hemisphere?

Why ask me? You are a consumate rejectionist.
Put it to test by placing a vertical at an angle
on a antenna optomizer program and see if it corrects the model to the
vertical. You could possibly reject all antenna computer programs on
that basis. As far as reactance is concerned it is real! That is why
we have the term "impedance"
Art

I was born in the docklands of London UK The naysayers or
rejectionists are all American. Could this be another case where
America imposes itself on science is to be viewed thru out the World?
Or are there no hams outside America using the same power of
communication (!.5 Kw) such they are forced to stand inline (and
behind)?

yep, all us real americans are suppressing your scientific genius so
that no one can ever make use of it! not that anyone with half a
brain would ever try.

OK for that.

I didn't test that until now. I will.

I better see what could be a home made tuner. Seems quite easy to
build :))

> This one tunes from 3.3 to 26 MHz. By changing the crocodile clips, you

The crocodile clips can be replaced by a selector. Am I OK on that?

> For the lower bands (AM broadcast) a loop may have advantage.

It is called a shielded loop. Am I wrong?

> Be careful with (expensive) loop antennas. If you can't get reception
> with a simple well-constructed (tuned) loop because of local
> interference (noise), the most expensive loop will not change that.

For now, I tried a lot of different things... The best result were on
loops.

A big loop (1.6mx4 = 6.4 meters), one turn, with an air variable capacitor + an inside loop connected to the coaxial cable seems to give better ways to give something to eat to my receiver. Sometimes my air capacitor was not powerful enough, in the lower bands if I remember well... To improve that I will have to add a fixed capacitor (lets say 300pF) in parallel (to be bypassed) or more depending on the band I am listening to. For now I am just experimenting (with some simple wire), but I think I will build a more solid one...

A big loop (1.6mx4 = 6.4 meters), one turn, with the the universal balun from Wellbrook. Don't know why, but, it gives very good results, far better than a long wire in my flat, or a short wire on my balcony... At this time it seems there is a Ham Contest in Italia... I can get them fully on 80m :) LSB/CW/RTTY... Well I live in South of France, so it is easier for me :)))

But the first solution seems more efficient. Need to do further investigations....

Sebastien.

"Art Unwin" wrote about his "tipped vertical" belief:
>Put it to test by placing a vertical at an angle on a antenna
>optomizer program and see if it corrects the model to the
>vertical.

Art:

1) Only YOU are the one espousing this belief.

2) Computer programs don't give the correct answer if the model is invalid, and/or its results are misunderstood by the user of that program.

3) Real-world, measured results may or may not support calculated results.

If your beliefs correspond to real-world performance, then YOU (and others) will be able to prove that using scientifically accurate methodologies in such real-world measurements. That result has been claimed by nobody, so far.

As this is YOUR peculiar belief, YOU should be willing to prove that it is true in the real world.

And if you are unable to do that, Art, perhaps you might see the wisdom in refraining to state and defend such a belief.

This is an excellent antenna for BCB and Tropical Bands.

The reason why this antenna performs so well is that it incorporates
the tuning function in the large loop - the smaller loop does the
matching. In other words, the large loop wire and the capacitor will
reject signals that could overpower your radio and create AGC that
reduces its sensitivity. It is, in effect, a tuner as we have already
discussed. It also happens to be your antenna too.

>But the first solution seems more efficient. Need to do further
>investigations....

One point to consider, this large loop will not perform the same when
its diameter is large when compared to the wavelength you are tuning
to. Your longwire with tuner will probably be better in the 50M band
and higher. However, experimentation may prove different, especially
if you can tip the loop over (or change its angle to earth).

Excellent, now share with the others how you were able to shoot me
down on my antenna theory that I am sharing with all. I want the
theory to be probed so I can rethink any errors
and put it right. Others are very anxious to shoot me down and would
just love your explanation as they do not have anything to work around
up to now
We now have been joined by another hyena
who was a radio engineer and is expressing his shock at the idea of a
tilted vertical, please help him out. When you have a vertical antenna
used for defensive purposes you really can't live with a" hole" in the
donut pattern. You must tilt it to close that hole in your defences so

that you have true omni pattern protection.

Strueth, so now computer programs are so difficult to use correctly
that they are worthless
A sailor came on the net a couple of weeks to show his ship with all
the antennas tilted so we have moved beyond the 20 th century tho many
of the sailboat are fighting the reasonability of doing that ! Many
old hams are convinced that "all is known" about antennas because
their era have found nothing that sheds new light and are content with
reading how to solder connections and discuss the meanings of a swr
readout. Now we have a new generation coming along and all are adament
they will all line up and sign on to the
lead provided by the present dying generation.

So what is your problem with the viewing of old theory and the efforts in generating a possible new approach? What is your problem with somebody other than yourself suggesting a new approach?
Years ago the hyenas on this thread denied that the boundary approach also leads to
Maxwells equations and we are not talking magnetics.A doctrate guy from MIT showed the math to support me but it was to late, he and now I are continually trashed for generating falsities with respect to ham radio. But for why?
Is there a fear that the self appointed experts
on the group may well be over estimating their thinking processes? Does it really matter that a proposal is provided that the experts want washed away? Experts can provide points that are debatable that will uproot faulty theorems so why do they feel forced to abandon true and tried methods of debate? State Farm has created a home for over a thousand teckies from overseas stating that what is available in this country is not equipped to do the job? Have we placed the old methods of debate and the approach to science while others advance?
Can we continue to deny that we are not the leading nation anymore while we are on this downward slope. You state that despite not obtaining a high school certificate you, a black boy, made it anyway and thus are able to deny all that you dislike shows a possible passage for Americas hopes, Think about it. Why are the
self ap,rized experts so determined that a new theory,, if correct, could take hold? What does the future hold if we try to continue the practices of the past which are responsible for our present position? What is the route you would like your grandchildren to take? Follow your path or strive for the new with curiosity. Industry today in America is asking for something better so good times can come back. Think about it! Is the example being set by this group sufficient for the future.

So back to the beginning, why does this group deny the extension to a Gaussin boundary in the form of a time variant current equals Maxwells equation? What good are these denials achieving by the actions of spam and insults?
Best regards
Art Unwin KB9MZ....xg

It depends upon how efficiency is measured. My more efficient car gets 30 MPG, My less efficient car gets 15 MPG. Any equation defining efficiency in terms of miles per gallon does not have a dimensionless result.

A meaningful measure of the efficiency of a transmitting antenna may relate to field strength per watt input, which is not dimensionless.

What is your equation?

> Typically you would have a portion in that equation that depicts

OK, but what equation are you using for an antenna that has those portions and where does L/C fit?

Now look at root L/C which points to the constitution of
> that which creates losses.
> Now ideally we would like this portion to be 1
> which states zero losses, an ideal situation.

Without providing your equation, we don't know how L/C fits. From what you say it is just some term out of nowhere.

> Thus we can say the losses involved equals
> root L/C which must equal "1" Logic therefore tells you that both L
> and C are loss leaders whether they be lumped or distributed and
> therefore not part of the vectors that create

How do L and C contribute to loss? Since current and voltage for each is out of phase, the power lost is 0. How do you reconcile this discrepancy with your position?

Remember for legitimacy all formulae must
> equal zero for equilibrium and therefore resolves into zero units. Now
> if you are unaware where root L/C
> appears in the study of radiation this is a good time to hit the books

Jim
You can deny the truth in what is stated above.
Your present position on science provides enough proof. Anybody can
view the archives
of "tom" "Jim" and others that you assume to see what manner of man
you are by your various accusations.
They can judge all your identities on their own without my help.
You too may have made it on your own without the required
education ,and deserve congratulations. But do you want others to
follow that same path and finish up just like you? What are your
motives with respect to your denials ? Would it not be better to
discuss antennas where one can learn and enjoy others?
Art

Tom. I don't trust you because of your prior posts but I am following
the norm where homework is for copying from the screen before
dismissal. As far as research goes their are many discussions
available that give support to my position so you have an avenue
to research for yourself without denial of mine.
If what you say is true regarding L and C then there is indeed a
problem. Provide a situation
where both inductors and capacitance do not provide losses and is
instrumental in creating propagation and I don't mind you providing an
excerpt from a book as to what is understood
as to how the losses incurred are part and parcel of the resultant
forces. Why not quote a formula on efficiency where the inefficiency
is not applied as a simple number but instead supplies the constituent
values that make up that number. I don't mind you quoting from the
books the same as I am doing. Think about it Tom, a capacitor
conserves energy and you know that an inductor provides a magnetic
field
by retaining half of what was supplied, Thus no amount of elements can
account for the disposition of all the power supplied.
Please note that I am not running away while missiles are being
thrown. I am stubborn ,and I am staying, and will respond, and I
certainly will not run away! I do thank you in your pursuit but in the
absence of believing me your answers will come from researching what I
state.
Why not start in stating what you do believe about my research ?
Gauss and Maxwell
Particles not waves
The actions of being diamagnetic
Levitation
Surface flow of current external to the radiator
and so on IN ORDER from my given description.
I need to see what base you are operating from
and what you do accept so I can build upon it.
I will stay with you. If you don't care about what I propose then take
leave of the thread because it lacks importance to you.
Best regards
Art

That isn't "efficiency", which is what is applies to antennas and it is
ALWAY a dimenionless number.

What you are talking about is "fuel efficiency", a different thing entirely.

The efficiency of a car is the useful energy output divided by the energy
in the fuel.

A modern gasoline automobile engine has an efficiency of around 35%, the
remaining 65% is mostly lost as heat in the exhaust.

Correct, you can use two selectors instead of the clips.

Correct. To have the balun function, the cut in the shield must be
opposite to the position where the feeder leaves the loop.

My experience is that at the lower bands (AM BC up to 3.6 MHz), loops
show better S/N ratio. However for the higher bands, performance
becomes similar to dipoles or monopoles. For reception I like the
small loops, as you can rotate them easily. They give less output,
but here tuning (even tuning inside close to the receiver) will
improve output (and noise….).

Regarding the large resonant loop with inside coupling loop, yes that
works well. I have a small one (0.6*0.4m) that tunes on the ham bands
from 3.6 to 30 MHz, it uses additional fixed capacitance for the lower
bands.
Unless you live in a very quiet environment, you can reduce the size
without sacrificing S/N ratio.

Thanks. I think I will try long wire again... I don't like to give up without fighting a little bit. But perhaps I will try it outdoor putting my receiver in the car outside any city or in a place where I get some place. So everything about antenna tuners need more investigation.

>>A big loop (1.6mx4 = 6.4 meters), one turn, with an air variable
>>capacitor + an inside loop connected to the coaxial cable seems to give
>>better ways to give something to eat to my receiver.
>
> This is an excellent antenna for BCB and Tropical Bands.

The problem seems to be related to wave propagation... I need to test that a little bit more but... It is easier to receive radio broadcast during the night. I need to know what are the differences between night/day for wave propagation. What should I listen during the night and what I should better listen during daylight...

I need to know a little bit more about digital transmission modes... To be able to recognize digital patterns (on the waterfall display) to be able apply the good settings for decoding... Easy for CW... Easy for RTTY used by HAM... But what is the pattern for Meteo Faxes for example...?

By the way... I searched for good free software to decode meteo faxes... But it seems not easy to find something free and easy to use... Do you know shere I could find something interesting?

>>Sometimes my air
>>capacitor was not powerful enough, in the lower bands if I remember

This is something I found on a website.... When you don't know anything about electronics... Your learning curve is quite flat :)))

>>For now I am just experimenting (with some simple wire), but I think I
>>will build a more solid one...
>>

>
> One point to consider, this large loop will not perform the same when
> its diameter is large when compared to the wavelength you are tuning to.
> Your longwire with tuner will probably be better in the 50M band and
> higher.

I need to make a tuner first... Then I will tell you about it.

> However, experimentation may prove different, especially if you
> can tip the loop over (or change its angle to earth).

Well.... not so easy for now... My "experimentation board" is a big wood shelf with a lot of books on it... Not so easy to flip, rotate or.... But it is well oriented (east-west) :)

My next tries will be on a multiple turns loops. With or without matching loop inside. I will try with simple wire but connection ribbon cables could be a good alternative... (like old hard drive ribbon cable)

I was wondering... It seems loop antennas are a never ending story. As far as I know, it seems there is no book that makes a good overview of the different loop designs, with accessible schematics for preamp or tuning stuff, how to avoid QRMs... There could be a very interesting area both for SWL and HAM...

Perhaps the "Joe Carr's Loop Antenna Handbook" may be interesting, but it is quite expensive and an Amazon reviewer says it is not so interesting... What about the "Joe Carr's Receiving Antenna Handbook" ?

Sebastien.

Efficiency is a measure so it must have one or more dimensions to have
relative meaning. The subject doesn't really matter. If Nigel Tufnel
says his antenna has an efficiency of 11 what does the number
represent beyond being one more efficient than ten? One more what?
Without any metadata the value is just a number, it just as well could
be 3.14159265 or 0xBADF00D.

A measure such as SWR might appear to be dimension-less because it is
a calculated value based upon dimensional values.

>What you are talking about is "fuel efficiency", a different thing entirely.
>
It's not really different, units consumed is a measure and units
traveled is a dimension. An attribute of the dimension is city or
highway driving. By adding metadata in the form of additional
dimensions, attributes and hierarchies more meaning can be given to
the measure.

>The efficiency of a car is the useful energy output divided by the energy
>in the fuel.
>
Limited dimensions suggest that 4 passenger vehicle's 40 MPG is more
fuel efficient than a 40 passenger bus getting 8 MPG. Add the
dimension of passengers carried, change the measure to passenger*miles
per gallon, and the bus (320 PMPG) becomes more fuel efficient than
the car (160 PMPG). More metadata provides more meaning to measures
which in turn provides better foundation information for effective
decision making.

In every case dimensions add meaning to the measure. The whole issue with Art's magic antennas is he values their efficiency by presenting measures that have no relative dimensions. The efficiency of his antennas may well be 11. The question remains eleven what?

in art's mind the efficiency of his antennas is 110%

Efficiency is a ratio usually expressed as a percentage and has no dimensions.

The efficiency of an antenna is the radiated power divided by the input
power.

Power divided by power has no dimensions.

The efficiency of an engine is the mechanical energy it produces divided by
the thermal energy of the fuel it uses.

Energy divided by energy has no dimensions.

Then how do you know it is multiband?

Your most specific request is for a folded dipole at one frequency.
From end-to-end it will be slightly less than 1/2 wavelength long at
that frequency.

Now, if you add another frequency, your folded dipole will need to be
1/2 wavelength long at that frequency.

Obviously to be "multiband" your folded dipole cannot be both lengths
at the same time. The requirment for the fold of the folded dipole is
obscure. A fan dipole would work for multiband.

>i use the diode as the switch to reconfigure the freq..later on i will

I have not the vaguest idea what that is about. "The diode"?

Joe
I have to apologize with respect to my stance on root L/C which is a
constant with respect to critical damping in R L C circuitry. For the
life of me I cannot retrace my thinking in the matter or my line of
thought, so that line of debate is just not on. However, if current
removes itself from an element to travel in a medium on the surface
and under a enclosing skin of particles
we have removed unwanted resistances from the equation as the
particles are in equilibrium
and their accelleration is now measurable. At the same time the medium
supplies a path for a ground vector.
Again I apologize for the path I led you
Regards
Art

The following aproach is not necessarily what I had in mind but root
L.C. is directly involved
in attaining oscillation for a given frequency and thus involved in
the resistance implied in the generation of oscillation required for
radiation.
It is this resistance that represents the other resistance involved
other than radiation resistance and removes itself from the element
to the medium between the entrapped element and the particles thus
leaving the radiation resistance on its own for the generation of
charge. A small amount of resistance will remain in the element in the
form of recoil from the levitating vector but it is extremely small.
I also see this resistance as the spoiler for perpetual motion of a
pendulum but that is departing from the subject at hand.
and can be neglected.
Art

Hi Sï¿½bastien,

What you are talking about is common to DXing. Get yourself a globe
of the world. Light it up with an artificial "sun." The edge of the
dark/light should be half way between you and the transmitter you want
to hear. So, during the late day, your best signals are probably from
Eastern Europe, Turkey, and Asia. During the early-to-late night,
your best signals are probably from the Americas. During the late
afternoon to early evening you best signals are from the south or the
north.

When I used to teach RTTY there were only two tones. If modem
technology is any indication, that number has been raised and phase is
important.

>By the way... I searched for good free software to decode meteo faxes...
>But it seems not easy to find something free and easy to use... Do you

Nope.

>My next tries will be on a multiple turns loops. With or without matching
>loop inside. I will try with simple wire but connection ribbon cables

This will reveal the "Law of Diminishing Returns" (the more you add,
the less you get back).

>tuning stuff, how to avoid QRMs... There could be a very interesting area
>both for SWL and HAM...

Oh, I am sure there are many such books gathering dust on shelves.
Loops have been around for more than a century, and if they were such
a good idea, then everyone would be using them.

Well, at one time they were a good idea, and EVERYONE used them - when
we had transistor pocket radios with analog tuning. The ferrite
antenna was the king of antennas for the vast majority of radio
owners. Before the transistor radio and ferrites, every table radio
had a flat pancake loop antenna in the back of the radio behind all
the glowing tubes.

Oddly enough, no radios in this age have either of these antennas
anymore, and they still seem to pick up stations.

So, there you have a century of technical perspective on the topic.

>Perhaps the "Joe Carr's Loop Antenna Handbook" may be interesting, but it
>is quite expensive and an Amazon reviewer says it is not so
>interesting... What about the "Joe Carr's Receiving Antenna Handbook" ?

He is a respected author. I always look at the bad Amazon reviews to
see if something is terribly wrong with the product or terribly wrong
with the customer. Quite often the customer is disappointed because
that customer is stupid. If I encounter a smart customer that is
disappointed, I can well imagine all the good comments are not very
reliable.

The thing about all these -um- books is that many of them serve up old
wives' tales about low noise and other magical characteristics.
Remember the lessons of a century worth of experience with loop
antennas within an inch of the guts of any radio. That worked fine
for a billion radios and radios were not bought if they were "noisy."

The real science of low noise is found in the distance to the source.
Quite often it is your neighbor's aquarium heater that is noisy (the
most often complained of source of noise reported here). Your loop
sits in your shack and that aquarium is 10 Meters away. You switch to
your longwire that runs to the fence and the aquarium is 1 meter away.
Do I have to work out the math on that? Is the loop quieter because
of its magic design - or simply because it is 10 times further away
(20dB) from the noise?

We get writers here who pound the table because their magic loop in
the shack is noisy and their long wire 10M away in the back yard is
quiet. They have to be told to turn off the flourescent light in the
shack if they want their magic loop to work.
(Their magic loop low score on Amazon) = (stupid.)

> don't worry we already neglect everything you say.

Well it is interesting to note that the oscillation of a radiater
inplanted the notion of a wave as the eye follows the change in
amplitude which led to the assumption that the medium entered after
leaving the radiator was the Aether of which the product of surface

wave came about.
Ofcource the medium entered is between the radiator and particle skin where one sees the optical effect on water. It is also interesting to note that element oscillations create a coefficient of discharge on current flow per Bernolli which creates our old friend of Eddy currents such that the two vectors of gravity and rotation continue to survive and where the separation of these two vectors produce light on collisions, but that is speculation on how equilibrium is restored
So as Einstein surmised, we followed the route of the two standard vectors or one depending on how you see it using boundary laws, from the containment of the Universe to light emmited from same. It is worthy of note that the helical twist model which represents the beginning of life is also represents the Standard Model as does the "curls" evident on a sea shell artifacts which simulates the equilibrium nature of the pancake antenna and that radiation can be explained by a "point action" (MoM) which also suggest that size or appature does not represent the path to maximum radiation ala the spiral or helical antenna in equilibrium.
Kraus was so close but the requirement of equilibrium (closed circuit) under boundary laws which he neglected brought him back to Earth.
A final note on the extension of Gauss
to the Maxwell equation. As for Einstein he correctly predicted the presence of the STD Model to radiation itself. A Genius no less

I came across a science dictionary of sorts by Eric Weinstein, the Nobel prize winner, which is the only reference that I have come across that verifies my explanation of the Gauss extension that everybody denies.
So if you are still rigid with respect to "waves":
you now have another person to rally against.
Regards to all

There are two dimensions in the calculation, radiated power and input power. Although the units of measure associated with the dimensional data may cancel the dimensional metadata doesn't.

80% is just a number where as 80% antenna efficiency provides meaning through the metadata. That metadata can also be properly expressed in terms of dimensions, the ratio of radiated power to input power is 80%. The units of measure may cancel but the dimensional metadata remains.

>
>Power divided by power has no dimensions.
>
>The efficiency of an engine is the mechanical energy it produces divided by
>the thermal energy of the fuel it uses.
>
>Energy divided by energy has no dimensions.

In both examples there are two dimensional values; the numerator and the denominator but the dimensional data as expressed contains no metadata. As a result the calculated measure is just a number with no meaning. Without metadata to describe the dimensional values, how can one determine which energy or power value is the numerator and which is the denominator? Energy divided by energy means it's a ratio so which is correct A/B or B/A? Until dimensional metadata is assigned the formula and its result have absolutely no meaning.

Don't confuse dimensions and dimensional metadata with units of measure. Dimensions contain data and the attributes of that data with UOM being a possible attribute. The descriptive value of the dimensional metadata remains even if the UOMs cancel in a calculation e.g. the ratio of radiated power to input power, no units just metadata. Without the metadata we're back to power divided by power yielding a meaningless number.

I apologize in providing a 'ratio' as a meaningless number and thank
you for the research undertaken by you to alert the group of my
meaningless error useage. I have assumed, wrongly, that percentage
was digital
sampling process to obtain productive and a non productive ratio
digital comparison or ratio in the base form of 100. If you have some
metadata to spare I request that you insert them for the record such
that the theme "baffle gab" is carried on for future readers. I also
request that you share your particular expertise in this matter with
other groups recognizing we all will be the true loosers if you decide
to depart
but I for one is willing to provide the hardship presented by your
absence for the good of all.
Regards
Art

x power/ y power = x/y

The units cancel to form a dimensionles, unitless, ratio.

This is grade school math.

The phrase "dimensional metadata" is meaningless babble.

Nothing you have written in this post makes sense but that should be
expected.

AFA metadata goes it is invaluable in data analysis applications
including antenna modeling programs. Every variable has its own
dimension containing potential values. Each combination of dimension
variables produces a measure known as a fact. Changing a single
dimensional value can change the value of the fact.

If one is modeling an antenna and changes the value of height above
ground, the calculated value of the measure will change. Height above
ground is only one of the many dimensional values used in the
calculation of the measure.

This all seems relevant because you question antenna modeling applications' calculations and how they are made.

I'll go back to lurking after I stretch so I can be looser. Enter OLAP or analysis cube for more information on metadata and its use in analysis applications.

Metadata is just a expanded project for archival analysis. It is not
intended to revise language
in various countries so scientific works and patent will not be
withdrawn by non conformance with the program by being termed
"meaningless" with respect to the new project.
The project has had numorous changes and revisions and certainly has
not yet arrived in its final form in libraries and archival uses in
computer programs There are no plans as yet to announce that most
scientific data is to be revised or declared illegal , patents
overturned etc Or the institution of such projects where computer
language will be taught in schools as a globalization of the new
speech or verbal communication of the day in the way Fortran was once
considered since thinkers of the computer era are still in a state of
flux as to what should be imposed and who has the authority to change.
There will be many enforcement programmers milling around to spread
virus regarding the program but generally these self appointed
programmers and the like are just trying to impose a new regime on the
public at hand via the imposition
of expansion regulations in a global fashion

no, that is classic art... pseudo random bafflegab that bears no
relation to the question that was posed and wanders off into unrelated
topics. the result of too much googling combined with lack of
knowledge and a need to explain the universe so he feels important.

unitless yes and in the example given no metadata is provided. The
result of the calculation is just a meaningless number.

What of the equation :
x units of radiated power / y units of input power
The units cancel but the metadata doesn't. The result is a number that
describes the ratio of radiated power to input power.

>The phrase "dimensional metadata" is meaningless babble.

You can call it meaningless babble but in its simplest form
dimensional metadata provides meaning and additional information to
raw data. You have used dimensional metadata in this thread and
unknowningly use it every day. The phrase "80% antenna efficiency"
contains both a unitless number and dimensional metadata. In this case
the metadata describes the dimensional calculation used to produce the
result. Remove the dimensional metadata and the phrase becomes "80%".
The latter has no context and conveys no meaningful information
because it represents a ratio of two unknowns. It could be a ratio
representing antenna efficiency or the price of apples compared to the
price of oranges. Raw data without metadata is meaningless babble.

2 watt / 10 watt = 0.2

No "metadata".

If the 2 watts is the radiated power of an antenna and the 10 watts is the
input power, the antenna efficiency is 0.2 or 20% since efficiency is normally
expressed as a percentage.

If the 2 watts is the output power of some circuit and the 10 watts is the
input power, the circuit has a gain of 0.2 or -7db.

If the input energy to a heat engine is 10 joules and the output energy is
2 joules, the efficiency of the engine is:

100 * (2 joule / 10 joule) = 20%

Yes, meaningless babble.

The phrase "antenna efficiency is 80%" says everything you need to know.

The phrase "engine efficiency is 35%" says everything yoy need to know.

And if antennas is the topic to begin with, the phrase "efficiency is 80%"
says everything you need to know.

No "dimensional metadata" required.

Actually, it doesn't - you are filling in the blanks with presumption.
Given that "efficiency" has been hijacked, the phrase above could as
easily relate to wind load. 80% survival rate at 100 mph. I could
well anticipate the counter-argument that "antenna efficiency" as you
intend it is power based, and I would counter-counter that power
delivered to the end user is far below 80% by 6 to 9 orders of
magnitude. There is nothing efficient about 79.999999% of the power
warming clouds and worms. HOWEVER, if the intended recipient receives
even that miniscule power with full quieting, then it is in fact 100%
efficient. In that regard, 80% and 100% as figures become meaningless
when they are both applied to the same statement of efficiency.

>In this case
>the metadata describes the dimensional calculation used to produce the
>result. Remove the dimensional metadata and the phrase becomes "80%".

No, efficiency in engineering terms has always been well understood
and does not embrace this adornment. In an earlier posting I've seen
the distinction of miles-per-gallon and passenger-miles-per-gallon
stretched over the argument to fit it to efficiency. No, these two
comparisons (and what you largely characterize as the need to include
Metadata) are "figure of merit" measures. FOM is also dimensionless
but demands the Metadata you speak of.

FOM could easily lead you into a very energy (the engineering
consideration) inefficient solution (due to social or economic
considerations, eg. passenger-miles-per-gallon).

Yes no metadata beyond the UOM and when the UOMs cancel the result is
a bare number. Twenty percent of what?

>If the 2 watts is the radiated power of an antenna and the 10 watts is the
>input power, the antenna efficiency is 0.2 or 20% since efficiency is normally
>expressed as a percentage.

Now you're adding metadata to provide information about what the 0.2
or 20% means.

>If the 2 watts is the output power of some circuit and the 10 watts is the
>input power, the circuit has a gain of 0.2 or -7db.
>
>If the input energy to a heat engine is 10 joules and the output energy is
>2 joules, the efficiency of the engine is:
>
>100 * (2 joule / 10 joule) = 20%

A selected calculated expression provides a ratio which resolved to a
value of three-tenths. Which of the three previously shown
expressions, if any, was selected to produced the result 0.3?

A - antenna efficiency
B - engine efficiency
C - circuit efficiency
D - none of the above

It's a simple question with no metadata provided about the calculated
expression arguments and no metadata associated with the result. In a
nutshell, no metadata what so ever. If metadata is unimportant then
there should be no problem answering the question.

Have you the slightest clue what the word "context" means?
```

"Antenna efficiency is 20%" has all the information required and if the discussion is about antennas, "efficiency is 20%" has all the information required.

I understand better what is the purpose of this kind of map (on SDR-Radio.com software for example). Where you can see an OM, you are pretty sure to see this kind of map.

>>I need to know a little bit more about digital transmission modes... To

OK. I will try that later... For now I get some problems to use Linrad with the SDR-IQ... Painful to boot on windows every time I want to listen to shortwaves... And using a virtual system is not very efficient on my old computer...

One thing handy about a small loop is you can turn it to
null out the offending noise. Like Richard says, there is no
magical quality which provides lower noise vs any other
antenna. The real benefit is being about to turn it, usually
while in the listening position. If the loop is well balanced,
the nulls are quite sharp and deep and in many cases you
could make that nasty noise source vanish. You can also
turn it to receive multiple stations that are on the same
frequency. You null the one you want to get rid of.
But these type of loops are best suited for the low bands.
LW, MW are where they are best suited. You get much
better nulls off a ground wave signal, than you do one
that is propagated via skywave. So they tend to work
better at nulls in the daytime vs at night. At night, you
get a mix of ground and sky wave, and the nulls are not
as deep. In the day, I can make most ground wave
signals totally vanish by nulling them out.
These can be used in the SW bands, but don't expect
the deep nulls, being as most all SW will come via sky wave.
For general SWL, you are usually better off with the various
wire antennas. Random wires, dipoles, etc..
But I recommend a small loop for MW if you want the
ability to null noise or undesired stations.
Most of mine, I build from PVC tubing for the frames.
I have one in this room that is a diamond, 42 inches
per side. It's on a stand which allows it to rotate, and
it stands almost as tall as the ceiling. But they don't
have to be that big. I've got another round one that is
about 16 inches across, and it works very well too.
Just a tad less signal than the big one. But the s/n

ratio is much the same for the majority of the stations
listened to.
http://home.comcast.net/~nm5k/loop5.jpg
This is my usual favored method for building a low cost
MW loop. The hardest part to come by these days is
the variable cap. I dig them out of old radios, and old
analog tuning stereo receivers. Those are some of
the best ones to use, as they often have several
gangs which can be wired in parallel for more
capacitance, or deleted for less. For the upper
tuning ranges of the loop, it's best to delete most
of the gangs, and use one of the very small ones
by itself.
That way you get a smaller value, and will increase
the upper tuning range, vs just turning all the gangs
in parallel to the minimum setting. So I use switches
to do this quickly.
But if you can't find any old radios to acquire the
variable caps, you can buy them online from a few
places. I wouldn't use one any less than a dual
365pf BC cap. You can wire the two gangs together
for 730 pf. With careful loop turn design, you can
usually cover the whole MW BC band with one of
those. But I prefer the ones out of old stereo receivers.
They are even better, and can give a wider tuning
range. I think the one on my big loop has four or
five gangs, some being small and useful for upper
end tuning, if the other larger gangs are switched out.

>The reason why they call you OM ? :))

Touchï¿½

>> This will reveal the "Law of Diminishing Returns" (the more you add, the
>> less you get back).
>
>Interesting. What would be the best ratio?

You mean the best number of turns? Depending upon band, maybe as many
as 6 to 10. One is good enough. There are many options to balance.
One correspondent here, years ago (silent key), wrote extensively on
this subject - google this group (or the internet) for Reg Edwards,
G4FGQ. For instance, google the keywords in:

RJELOOP1 *
Performance of Transceiving, single-turn, magloop antennas of various
regular shapes.

RJELOOP2 *
Performance of Transceiving, single-turn, magloop antennas of
rectangular shape.

RJELOOP3 *
Analysis of receiving, multi-turn, square, loop (or frame) antennas,
ELF to HF.

>I will try to find one when they are cheaper.

Try:
http://www.bookfinder.com/search/?author=&title=Joe+Carr%27s+Receiving+Antenna+Handbook&lang=en&isbn=&submit=Begin+search&new_used=*&destination=us&currency=USD&mode=basic&st=sr&ac=qr

>OK. But today we probably ask more to radios than yesterday, no?

No, probably less. Being an OM, (40 years ago) I also taught classes
for repair and maintenance of Collins' famous receiver, the R-390.
EVEN NOW (40 years later), this is probably the best receiver for its
price (and even two to three times its price).

>> The real science of low noise is found in the distance to the source.

Precisely why metadata is so important to describe data.The generic
term 'antenna efficiency' does not provide enough metadata to describe
the true meaning of the measure. Some additional metadata turns the
potentially ambiguous "80% antenna efficiency" into "the antenna's
radiated power divided by its input power results in a percentage of
80%"

>
>No, efficiency in engineering terms has always been well understood
>and does not embrace this adornment.

There are many different expressions that calculate efficiency, so
wouldn't the adornment be the context aka metadata which describes the
expression used to calculate the result? If I write "80% efficiency"on
a piece of paper and hand it to an engineer, how can the engineer know
what is 80% efficient without any metadata being provided?

> In an earlier posting I've seen
>the distinction of miles-per-gallon and passenger-miles-per-gallon
>stretched over the argument to fit it to efficiency. No, these two

>comparisons (and what you largely characterize as the need to include

>but demands the Metadata you speak of.
>
The last sentence tells me you get it. 80% is a FOM with no UOM so for
the value to have meaning metadata must be provided.

>FOM could easily lead you into a very energy (the engineering
>consideration) inefficient solution (due to social or economic
>considerations, eg. passenger-miles-per-gallon).
>

The whole purpose of data analysis is to aid in effective decision
making. Pretty much every decision requires some sort of trade-off.
By analyzing and reporting upon the expression results that different
combinations of dimension values provide, more information can be
provided the decision makers. The decision makers are the ones who
specify what data they wish to view (both dimensional data and the
results of multi-dimensional expressions) and the ways they wish to
view that data. All that information is placed in a multi-dimensional
cube. The decision makers can slice and dice the cube data into how
they want to view the data and determine relative FOMs for multiple
scenarios. Their questions are which scenario model is most suitable
and does the most suitable scenario provide a valid solution for the
problem.

AFA the passenger-miles-per-gallon calculation, the decision makers
could decide that more information is needed in terms of greater
granularity. Changing the granularity to stop-by-stop and providing
associated passenger and fuel consumption statistics will deliver more
information. The decision makers could also ask for data that
provides social and economic information. The multidimensional PMPG
expression could be changed to include the social and economic data.
More data and metadata provides more information.

The form of desired social and economic data and how it is to be used
in expressions is something the decision makers must determine. All
the information about required cube dimensions, attributes,
hierarchies, expressions, etc, are determined by the decision makers.
Those who build and load the structure have little say in the matter,
the decision makers decide what data and metadata is useful for their
analysis.

An image of a simple multi-dimensional cube can be seen at
http://books.google.com/books?id=AFC4IbrEJuAC&lpg=PA21&dq=Delivering%20Business%20Intellig
ence%20with%20MSSQL%202008&pg=PA34#v=onepage&q&f=false
or
http://tinyurl.com/337m42z

Each dimensional intersection uses the same multi-dimensional
expression (MDX) to provide a result. The UOM at each intersection is
the same (dollars) but the results differ because different sets of

dimensional arguments are used in the MDX. The amount $3,156,834 is raw data but the cube tells us it represents total sales for the Mythic World product in 2005. That metadata must be used to describe the result if that value is to be used away from the cube.

Change that cube's dimensions and the values they contain to be antenna-related, add a few more antenna-related dimensions and attributes, create some expressions that use dimension values to provide appropriate measures and the structure could be used for antenna analysis.

The phrase "antenna efficiency" is non-dimensional metadata
and to quote Mr. Clark
-quote-
Given that "efficiency" has been hijacked, the phrase above could as
easily relate to wind load.
-end quote-

>The phrase "engine efficiency is 35%" says everything yoy need to know.
>
You assume that engine efficiency is only and always measured in terms
of energy efficiency. Engine efficiency can mean different things to
different people. There are other expression which are also used to
calculate engine efficiency including fuel economy, power-to-weight
ratio, and power-to-displacement ratio. The respective UOMs for those
measures can be expressed as miles per gallon, hp/lb. and hp/cid. For
these calculated measures "engine efficiency is 35%" is not suitable
result.

>And if antennas is the topic to begin with, the phrase "efficiency is 80%"
>says everything you need to know.
>
>No "dimensional metadata" required.

Non-dimensional metadata (antennas) is provided as the topic and the
result contains non-dimensional metadata (efficiency) as well. As Mr.
Clark pointed out "antenna efficiency" is a potentially ambiguous
phrase. Such ambiguity can be eliminated by using dimensional metadata
e.g. antenna efficiency calculated as the ratio of power radiated to
input power. With the measure qualified as such an individual reading
a summarized report doesn't have to be party to yesterday's discussion
or know the exact expression used in the calculation or infer meaning
from ambiguous metadata such as "antenna efficiency". The phrase "80%
antenna efficiency calculated as the ratio of power radiated to input

power" explicitly provides the proper meaning to the calculated result.

Of course it is, that is basic physics and the definition.

Other things are other things and have qualifiers, especially if they use
the word "efficiency", otherwise it is just ignorant babble.

<snip babble>

The phrase in question is "dimensional metadata" and now you are switching
the subject to "non-dimensional metadata".

> As Mr.
> Clark pointed out "antenna efficiency" is a potentially ambiguous
> phrase. Such ambiguity can be eliminated by using dimensional metadata

> e.g. antenna efficiency calculated as the ratio of power radiated to

The definition of antenna efficiency is the "ratio of power radiated to
input power", so stating that is redundant.

<snip more babble>

I suppose you argue with writers of recipes when they say "add 1 cup of milk"
saying they should say "pour milk into a measuring cup, that is a cup used for
measuring liquids, until the milk level, that is the level in the measuring
cup, reaches the mark on the measuring that denotes the meauring cup contains
1 fluid cup, in this case the milk, then pour the contents of the measuring
cup into..".

The engineer would use the context under which the number was provided.

If there were no context the engineer would be justified in concluding that
you were a babbling mental case.

Absolutely, yes I do. In turn I will ask do you know what metadata is?
Both dimensional and non-dimensional metadata provide context.
Non-dimensional metadata doesn't always provide the complete context.
Dimensional metadata provides greater context because it conveys more
detailed and specific information.

>"Antenna efficiency is 20%" has all the information required and if the
>discussion is about antennas, "efficiency is 20%" has all the information
>required.

When data gets shared among multiple parties it is important that a
ubiquitous language is used to describe the data and its meaning.
Antenna efficiency can be measured in different ways so the phrase
"antenna efficiency is 20%" can mean different things to different
people. All it takes is one person to ask how antenna efficiency is
calculated and it will become evident that context of "antenna
efficiency is 20%" does not provide all the information required.

When the result's context includes dimensional metadata such as "20%
antenna efficiency calculated as the ratio of power radiated to input
power" the meaning of the result and how it was calculated both are
self-evident. Everyone knows what the result means because the
dimensional metadata provides an exact definition. A mere ten words of
dimensional metadata adds succinct clarity to the result. What makes
such clarity unnecessary and/or undesirable?

> efficiency is 20%" does not provide all the information required.

Sure it does. Antenna efficiency is only calculated one way,
so there is no need to add extra "metadata".
Like one said, it's redundant. In the real world, most will
calculate the efficiency of the antenna system as a whole.
Not just the radiating element/s. Even a very small dipole
vs wavelength will radiate nearly all power that is applied to it.
The trick is actually getting the power to it without it turning to
heat.
So most will calculate the whole system, otherwise it's
fairly pointless. But the efficiency of even a whole system is
still calculated the same way, and no extra "metadata" is
required to calculate. It's still the ratio between the output of the
transmitter, vs the RF actually radiated. It's been that way
since they invented dirt, so who needs metadata? I sure don't.

I'm starting to think it must be a full moon...
It's been getting pretty silly around here lately.. :/

Hello Sébastien,

Regarding tuning, loops and (long) wires.

You probably locate your antenna far away from noise sources. Mostly this is not where your receiver is.

In case of tuned loops, you have to go outside for each significant frequency change. This is one of the reasons that I want my preselection / tuning adjacent to the receiver.

Loops aren't magic things. A wire from your balcony to a tree or other tie point may give better S/N ratio then the best (expensive) loop on your balcony.

Best matching isn't required for reception at HF, just sufficient signal. In case of a PI tuning / preselector device, you need to adjust two capacitors in case of major frequency change. In my opinion a single capacitor device is more pleasant to use.

(deep) Nulls in the radiation pattern at low frequency (AM BC and below) are the main benefit of the loop if you are willing to change the orientation frequently when tuning across the bands. At increasing frequency, the nulls are less pronounced because of propagation issues. Off course a small horizontally oriented dipole has also figure-of-eight radiation pattern, but polarization isn't good for AM BC and lower.

For experimentation / comparison, I used a 1m diameter non-tuned loop in the attic with preselection / tuning adjacent to the receiver. In most cases a 5 m outdoor wire with same preselector and receiver gives similar or better S/N ratio. This may be because of the attic has mains wiring and I didn't want to go to the attic for reorientation of the loop.

If you want to experiment with some long wire (unbalanced) antennas, make sure to have a ground (counterpoise) provision outside; otherwise your coaxial cable will be part of the antenna. This may result in more interference from indoor sources.

Whether or not you have sufficient signal from your antenna is easy to check. Listen to a known station. Tune your preselector to maximum signal. Now tune to a free frequency close to your station's frequency so that you hear noise. Remove the antenna, the audio noise should be less now.

If you use a tapped coil preselector (like the one in my link), and have sufficient noise from the antenna, you may even change the taps. The preselector will give more insertion loss, but it will be more selective also. This can be of use when you have strong signals in your neighborhood. Because of portability, I frequently use an AOR

AR8200. Without preselection, such a wide band receiver is useless
with an external antenna.

Best regards,

really? i don't see either 'efficiency' or 'antenna efficiency' in
either my 2nd edition of jackson's classical electrodynamics, or
ramo,whinnery, and van duzer's fields and waves in communication
electronics... if you know where those terms might be defined in
either of those please let me know, maybe the indexes aren't complete
or something.

Gentlemen
This metadata project is only about substituting a machine for a human
being. Human beings have a brain and it is not necessary to overload a
brain with information that the brain does not require to function.

Regisered User and some other guy arrive at a gas station at the same time.

Other guy: "Fill'er up."

Regisered User: "Remove the gas cap, that is the covering device on the gas tank, that is the tank, which is an enclosure, which holds the gasoline for this car, that is a private passenger vehicle, and dispense gasoline from your pump, that is the mechanism that dispenses gasoline, into the tank, that is the tank intended to hold gasoline, until the fluid, in this case gasoline, level, which is the fluid air, which is 78.1% nitorgen, 20.9% oxygen, 0.9% argon and less than .1% other trace gases, interface, which forms because we are on a planet with positive gravity, reaches the top, that is the uppper most part, of the gasoline tank which holds the gasoline."

This is followed by a 20 minute dissertation on which way to turn the gas cap to get it on and off, an explanation of how the percentages of the various gasses than make up air are measured, the origin and history of the gallon, and the value of the dollar relative to a loaf of bread in 1937.

really? i don't see either 'efficiency' or 'antenna efficiency' in
either my 2nd edition of jackson's classical electrodynamics, or
ramo,whinnery, and van duzer's fields and waves in communication
electronics... if you know where those terms might be defined in
either of those please let me know, maybe the indexes aren't complete
or something.

well, i kept looking.. arrl antenna book doesn't have it, but mine is rather old maybe more recent ones have it.

aha! found efficiency in the ieee handbook of antenna design... but it has subtopics:
aperture
beam
cassegrain
cross-polar
depolarisation in offset reflectors
illumination
offset antennas
polarisation
radiation

now exactly which definition do you consider the 'unique and unambiguous' one??

So, by this you agree that your original metadata was not useful. As
for it being "dimensional" there was nothing dimensional expressed nor
offered by you afterward in further elaboration.

>The whole purpose of data analysis is to aid in effective decision
>making.

Metadata is useful in Figure of Merit and such is the entirety of your
argument.

Unfortunately, the only thing revealed here is that your metadata is a
portmanteau word covering an infinite regression of refining
statements. We would be better served in consideration of the Figure
of Merit side of the discussion where many could easily discard a lot
of metadata deadwood.

That is the practice of engineering.

Compounding unfortune, Art is incapable of providing weighted values
to make progress in any discussion. There is no Figure of Merit
consideration, there is only the combinatorial explosion of
possibilities. That has lead us through the dimensions of 180 meter
wavelengths to the sub nanometer relativistic effects of nuclear
physics - all treated with equal importance such that practicality has
been debased.

This is the Art of science fiction, metaphysics, or religion.

I understand what you write, but not why you choose this arrangement.
I can guess many configurations, but your goal is obscure.

Inventive to say the least.

Conventional antenna design already has passive solutions for your
active element requirement and they stand the chance of reducing the
risks inherent in putting a diode into an antenna structure for
switching its length.

The one that one normally means when not using a qualifier, radiation.

but your basic point still fails... the definition of efficiency is not universal, unique, nor unambiguous since it is not in ALL textbooks, nor is it a simple single definition, as my list of qualifiers in the ieee handbook illustrates.... oh, and those many definitions are not just restating the same thing, they are VERY different definitions depending on the aspect of the antenna you are studying.

The fact that it is not in all textbooks is irrelvant.

Not everything is in all textbooks of any kind.

There are many scientific and engineering terms that can have qualifiers
to denote specificity.

And in most every case there is a qualified term that is in most common
use and is commonly used without the qualifier.

Every engineer I know when discusssing antennas in general that say "antenna
efficieny" mean "antenna radiation efficiency".

The ARRL Antenna Handbook, when talking about "antenna efficieny", refers
to "antenna radiation efficiency".

For most of the links of the 7,000,000 or so when you search for "antenna
efficieny" you come to a link that refers to "antenna radiation efficiency".

ah, so you have performed a contextual statistical analysis on 7M
links in the last half hour... thats pretty good processing. what you
got for a computer there?

No, I looked at the first four and all of them were referring to "antenna
radiation efficiency".

Then I scanned the summaries that Google gives for the first page of hits
and found that all but one referred to "antenna radiation efficiency".

The one exception was on a page about satellite calculations and they
were referring to "antenna aperature efficieny", as would be expected from
the context.

oh, so from skimming a dozen links and only finding one who's apparent reference wasn't what you were looking for that makes 'most' of the other 7M fit your definition also. i know that polling works for politicians to declare that they are going to win by only asking a few hundred out of millions, but at least they don't just ask the first few people they meet on the street and assume that they represent the rest of the country.

It is called statistical sampling and is most appropriate for Google as
the links returned are ordered by relevance.

I do note you have nothing to say about the other two statements; what, no
nits to pick there?

no, i'm having enough fun with this nit.

> no, i'm having enough fun with this nit.

Well nit this, as I said Google links are ordered by relevance and starting
on the second page you begin to find links to information about the efficiency
of a specific antenna as opposed to efficiency in general.

If you limit the results to about 57,000 results by putting antenna efficiency
in quotes, it is pretty much all specific to an antenna by the third page.

Yet the first page doesn't change.

great, now why don't you try some negative searches for the other
specific terms that i quoted from the ieee book and see how many links
show up for them, then compare the relative numbers of links and their
order with the original search... that should keep you busy for a
while.

I find that a funny thing, since they define two different things.
They are not the same thing, and should not be confused,
intermingled, or even paired up on the same date to go watch
Star Wars at the midnight movies.
If I were to refer to aperture efficiency, I would call it aperture
efficiency, effective aperture, or maybe even antenna effective
area, but not antenna efficiency.

It took about 10 seconds to cut and paste.

11,000 results with 7 out of 10 of the top results identical.

It appears your efficiency in attempting to deride what I've said is deficient.

Joe,
a better insight to my thinking that may help
When a member has little or no reactance via cancellation you can use
V=I.R.
When R becomes exceedingly small the member reaches a critical point
and will oscillate
When this happens current increases dramatically which therefore
increases radiation. If you view the current curve on a dipole the
current is of cyclic form whereas in the case where critical
resistance is reached
the current flow is of a very high value pulse which also drops fairly
rapidly until it reaches a low point before it gets to the end of a
period.
When the element oscillates it has become a mechanical movement BELOW
the current path
and as can be seen by comparing to water flow
the raggednes in terms of cross sectional area of flow has createrd
eddy currents which in electrical terms is equal to displacement
current
as it is the creation of displacement current.or coefficient of
discharge
This states why magnetics as used in non equilibrium structures such
as the Yagi cannot be as efficient as a Meander form which achieves
higher current which propels or provides for radiation..

What propelled the notion of waves instead of particles is 1 they ignored Gaussian thrust towards equilibrium and 2 turned to the increase in current because of the mechanical "wave" action which only provides change in amplitude which is not enough to provide an acceleration of charge on a particle resting on
water since that requires two vectors.(I say a resting particle where as it was never clear what the "wave" was lifting or where it came from. This because the force required to remove an electron from its element habitat
required more force than that was available.
(Gravity is termed as the weaker force in the Std model)
The bottom line being, a radiating structure in equilibrium devoid of reactance with low resistance is the only way current over and above that supplied becomes available.
By the way the std yagi is not a closed circuit
as equilibrium requires because the half wave length floats, where as a full wave or "period"
is consistent or in a steady state when "overshoot" occurs. Thus only when it is resonant is it devoid of reactance which limits the bandwidth. In the case of a Meander form
the magnetic field is not present in cyclic form
allowing for surface current flow for extended periods and is not frequency dependant.
As I have stated before, with my antenna current distribution is via a surge with rapid decay which is accepted in RC L circuitry.
Hope that clears things up for you
Regards
Art

The IEEE Standard Definitions Terms for Antennas (IEEE Std 145-1993) provides no definition for 'antenna efficiency' per se. A definition is provided for 'antenna efficiency of an aperture-type antenna' in section 2.15 of the document. The definitions are in alphabetical order so the definition describing the ratio of power radiated to input power appears in section 2.308 which is titled 'radiation efficiency' (notice the dimensional metadata).

These citations from IEEE Standard Definitions Terms for Antennas clearly suggest claims of a universal formula and definition for antenna efficiency are incorrect. Not everyone means the same although they use the same name. This is why it is important to define or refer to the definitions that are used.

So what?

The term is in common use and can by found in many textbooks on
electromagnetics in general and antennas in particular, several books by
the ARRL as well as on many technical web pages.

So the fact that a particular IEEE standard does not mention a term that
is in common use is irrelevant to the fact that the term is in common use.

Prognostication expressed as a blanket statement often fails to consider possible/probable exceptions to the rule. When such blanket statements are shown to be flawed the prognosticator starts back-pedaling as to what was meant and should have been written. Finally the prognosticator decides the blanket statement wasn't all that important to begin with.

The post concerning "a unique and unambigous definition" which "can be found in any textbook on electromagnetics" and subsequent back-pedaling appears to fit that model. Your "So what?" provides the meh.

You took what may be a perfectly valid general rule, tried to convert it to an absolute certainty, and failed. That's so what.

That's an interesting concept. The difference between ground and sky
waves and the way to use loops. And small loops are easier to make...

> Most of mine, I build from PVC tubing for the frames.

A simple, but good idea. PVC tubing is inexpensive and quite rigid...

I got one and I am searching for others. It seems that variable caps are
one of the center of a lot of things in radio reception :))

I can see on the loop5.jpg image that you connected one wire to the
ground and one wire to both other connections (double gang capacitor) so
that you add the result of both capacitors. Is that correct?

> That way you get a smaller value, and will increase the upper tuning
> range, vs just turning all the gangs in parallel to the minimum setting.

> out.

I found a 500pF + 500pF one too, with a slow motion drive. Another way to drive them slowly is to get a 20cm (10 inches) piece of wood, perforate it on one side to put the capacitor axis into the hole (put some glue, but a smaller hole is better, and push it hard so that the axis enters inside the hole), and you get something that can be tune very precisely with one finger... About the piece of wood, the longer, the higher in precision tuning.

Sebastien.

Yeah, the "back-pedaling" which consisted of changing "any textbook" to
"many textbooks".

And nowhere did I reference any standard, IEEE, ISO, or any other standards
body.

<snip remaining long winded babble>

Do you calculate that in constant dollar from the 50's? :)

I can imagine the teaching class. Everybody with a Collin's in front of him/her... A one year project to restore completely one of this legendary radio. I would like that!

With a good DSP outside (Audio DSP only), can beat every other ones?

It seems not easy to get one, especially in Europe...

That's a problem, indeed.

> frequency change. This is one of the reasons that I want my
> preselection / tuning adjacent to the receiver.

It seems there is another solution. The varactor diodes seem to act as a variable capacitor driven by their voltage (the capacitance of this kind of diode decreases as the potential is increased).

It seems there are some loop designs with varactor diodes as tuners.

But I don't know what could be the price of a such solution.

> Loops aren't magic things. A wire from your balcony to a tree or other

I think so, but there is nothing I can change for that today.

I will try different configurations when I get them.

Yes, but the place I plan to experiment should be far away from this kind of trouble... I won't be able to get a good ground there.

> If you use a tapped coil preselector (like the one in my link),

Sorry, where is it in your web site?

> and have

How is called this design?

> This can be of use when you have strong signals in your
> neighborhood. Because of portability, I frequently use an AOR AR8200.
> Without preselection, such a wide band receiver is useless with an
> external antenna.

I don't like these receivers... Or they should be used with optoelectronics frequency counters to drive the receiver... But more than that, the screen of these receivers is too small, too few information... I prefer being at home (or in a car) with a laptop computer displaying a beautiful waterfall picture :))

That's the reason why I owned a SDR-IQ. And on upper frequencies, it will keep being useful with an appropriate scanner (if I see a cheap one on the second hand market).

For the moment, I prefer exploring the bands than picking up a frequency in a database (it may change...)

Sebastien.

If this is so important to you, I am sure you will be researching all
the electromagnetics textbooks, antenna texbooks, industry and trade
publications, the ARRL, the RSGB, manufacturers, and everyone else with
any interest in antennas to determine the "correct" usage and definition
of the terms in question, and submitting a draft proposal to the IEEE.

nope, i don't care that much, but you sure seem to be insisting there
is a correct usage when obviously it hasn't ever been really agreed
upon by the right people. so you are the one who should be trying to

get all the worlds authors to agree to define it the same way and get
it into all the text books where its been missing all these years.

>radio. I would like that!

There were two to a radio. 40 to 30 hours learning the schematic
theory of operation; and troubleshooting and tuning procedures and 30
to 40 hours in front of the radio. The class was 2 weeks long.
Complete restore unnessecary, of course, as the last class had fixed
any problem. No, we had a data bank of known problems, known
solutions, and the time to debug them averaged over at least 100
students for each problem.

>With a good DSP outside (Audio DSP only), can beat every other ones?

Good for filtering, probably tighter than the mechanical filters
(theoretically), but there are many, many other considerations.

So if the IEEE doesn't mention it in some standard everyone else is wrong?

Since there are electromagnetics textbooks, antenna texbooks, ARRL books and web sites that all say the same thing, it appears there is some agreement out there in the real world.

As for what's missing in some selection of books, I'm quite sure that if you do a comparison of every book on a given subject there will be differences in the topics covered.

That would be babble about why making blanket statements without
adequate research is not an effective decision. That is what you did
isn't it? Does everything that questions your highly self-valued input
become babble?

On Tue, 14 Dec 2010 16:54:40 -0000, jimp@specsol.spam.sux.com wrote:

>The term "antenna efficiency" has a unique and unambigous definition and
>can be found in any textbook on electromagnetics.

Speaking of babble, which parts of that statement have been shown to
be true? The balance can truly be considered babble.

>> The post concerning "a unique and unambigous definition" which "can be
>> found in any textbook on electromagnetics" and subsequent
>> back-pedaling appears to fit that model. Your "So what?" provides the
>> meh.
>
>Yeah, the "back-pedaling" which consisted of changing "any textbook" to
>"many textbooks".
>
And let us not overlook how the "a unique and unambigous definition"
became "the term is in common use". Adding conditionals to what was a
statement of absolute certainty does not make the original assertion
any less flawed. That's just woulda, coulda, shoulda revisionism, an
attempt to change the question to make it better fit the known answer.
What makes that path better than the simple admission of having made a
mistake?

>And nowhere did I reference any standard, IEEE, ISO, or any other standards
>body.
>

Yep you made no reference to any standards except for the ones you made up. Now you're making excuses for failing to refer to any other standards before making assertions which turned out to be wrong.. Alibi all you wish but the flaws in your assertion of "a unique and unambigous definition" which "can be found in any textbook on electromagnetics" have been exposed.

><snip remaining long winded babble>

What you call long-winded babble was

- quote -

You took what may be a perfectly valid general rule, tried to convert it to an absolute certainty, and failed. That's so what.

- end quote -

How could those two sentences be made to contain less babble and be made more concise?

Denigrate the messenger all you wish but that will not change the fact your blanket statement was nothing more than an uneducated, unfounded opinion. Please note I refer to the opinion as being uneducated and unfounded not the individual. Whatever your education, skills and experience are, the aggregate is unrelated to the fact you come across in the context of a small person who is rather full of himself. Let me just pat you on the head and say 'you win, you're right because you say so'.

That is an option, as they are frequently used in VHF/UHF systems. The
varactor is a non-linear device, so you may get intermodulation in a
large signal environment. You may use the varactor as fine tuning in
combination with fixed capacitors.

I don't know the name for it, it is just a parallel resonant LC
circuit where the input and output goes via an inductive tap. Moving
the tap changes the coupling between the source/load and the resonant
circuit, hance changing the loaded Q-factor.

I fully agree on your statement, as these wide band receivers have
poor large signal performance, and don't have waterfall display....
However sometimes portability is of importance and then they can be
useful.

Hello,

Not too sharp with antenna and noise theory, so please bear with me a bit.

If I have a run of coax from a Balun right at my outside receiving only
antenna (well grounded at that point) right to my receiver, is it still
possible to have common-mode noise induced into the coax ?

Say from a PC, Modem, Router near the receiver.

Wouldn't the coax shied prevent this ?
If not, why not ?

Can't picture how an emi source field would/could "get-thru" the coax
shield to the inner conductor.

Thanks,
Bob

It doesn't have to. The inner shield and outer shield are shorted
together at the chassis. If noise exists on the chassis, i.e. the
chassis is not really "ground", the result is differential noise on an
unbalanced input. Essentially the same thing happens when SWR meter
readings are affected by common-mode signals during transmit or when
an unbalanced antenna analyzer is connected to balanced feedline
without a choke. A good choke on the coax near the chassis often
reduces the magnitude of the problem in all of the above cases.

>
> Do you tune it, or not? Is there a small loop inside or not?

Yes for both. The cap is down at the bottom corner, and
I use a separate coupling loop because I'm feeding coax
to the radio. The 42 inch per side loop uses 5 turns on
the main loop. The coupling loop is on the inside, and
maybe 36 or so inches out from center.
Sounds like you are in good shape for caps.
That 500-500 would be good. I'd put a small mini switch
between the two gangs to be able to cut or add the
second gang. That's what I do on mine anyway.
I solder the switches right to the tabs on the cap.
I also have a handful of fixed caps to add if I want to
drop further down into longwave. I don't use them that
often so I just clip them on if needed.
I think my 16 inch round loop has about 12 turns if
I remember right.. It also uses a inner coupling loop.
For me, those loops are mainly for AM-BC, but I do
wander down and listen to the air beacons from time
to time. And the big one covers 160 meters, so I
use it for that sometimes.

Hi,

Thanks for help; appreciate it.

I wasn't too clear.

By the "inner shield," I mean the signal carrying innermost (solid)
conductor of the coax.

Guess I am wondering how can emi noise get thru the outer shield and to
the signal carrying conductor. Unless, of course, it's a really poor
outer and leaky outer shield.

Regards, and thanks again,
Bob

>
> It is the simple thing I referenced earlier
> www.tetech.nl/divers/SimplePreselector2.jpg

Sorry... Yes, your design seems quite simple. But as a beginer, I think i
get some problems to understand how things are connected to the variable
capacitor, I mean I think the way the variable capacitor works is missing
in my information pool...

Based on your photo let say we get :
On the upper side : two connectors
On the lower side : two other connectors

But the upper side connectors are connected to the lower side
connectors... via the capacitor itself. Am I right?

The tap coil preselectors seem quite easy to carry out. You use different connectors on the tap to select the band you want to use.

You get a switch on the upper side that seems to avoid using one gang of the capacitor... But I cannot see of it is connected to the ground or not.

The air capacitor ground is connected to the ground.
On the right side, the tap coil preselectors are connected to the ground too.
There is a tiny capacitor that connects one gang to the ground again.

The central board should be used to avoid both tapped coil preselectors to get an inductive action on the other?

Is this correct? Would it be possible to get the schematic so that I could try to carry it out?

How did you compute the place to put the connectors (number of turns) for the tapped coil connectors?

>> > and have

Hello Sébastien,

This: http://www.tetech.nl/divers/Simple_HF_Preselector1.png will help you. It shows the basic idea of a simple single variable capacitor preselector.

You can use one coil and put two selectors on it, but with two seperate coils the attenuation for out-of-band signals is much better. This is because the individual turns of each coil have low mutual coupling (they don't act as a transformer). As I have sufficient antenna noise, the selectors (in my case clips) are mostly on the lowest position (I don't need matching to get more signal and noise).

For AM BC operation you need more turns (w.r.t. the coils on the photo).

One key point here is that the coaxial cable shield is grounded at two points, at the receiver and at the antenna. You might have what is known as a ground-loop. The best thing to do is to ground the receiver, the computer, the modem, and the router with leads as short as possible, AND TO THE SAME GROUND POINT. Since you have a balanced to unbalanced conversion (Balun) at the antenna, there is no need to ground the coax shield at this point.

Years ago, I had three grounds in my ham shack: the power line ground at the service entrance to the house, the tower ground where I had mounted a rotary coax relay, and a copper cold water pipe running beneath the shack which connected to the buried galvanized water pipe running from the street to the house. I measured from 3 to 15 volts AC between the three grounds. When connecting them together, I measured as much as an amp of current flowing. I bonded everything together at the water pipe and used this as the single point ground to which everything else was grounded.

I agree with Cecil that the noise is probably common mode noise. But the quality of the coax certainly does affect how much signal leaks in or out of a coaxial cable. I haven't bought Radio Shack coax in years, but it used to be very poorly shielded. The braid shield looked more like window screen than it did a solid sheath. This is the reason most CATV providers use flexible coax with two shields: a foil or metalized plastic

shield covered by the braid shield. Special coaxial cables with high leakage are often used in long tunnels to provide FM reception in the tunnel.

I'm really short of space for antennas, but I think I might be able to get away with one of the small HF beams I see advertised if it could be mounted on a roof-top tripod. Dimensionally, I think a conventional 3-element beam would fit, but I don't think a roof-top mount would be adequate.

Are any of these even worth considering?

I came by it while demolishing a motel. A roll of green rope was in
storage there. Dont know what it would cost if I had to buy it. Hemp
rope is cheap if you can find some that is raw and not impregnated
with oil it should take resin pretty good. Fortunately the kind with
no oil is the cheapest. Ive experimented with rope made of paper,
soaking it with resin also made some rods I believe could be used for
your pupose. I never used them for anything but they I had a couple of

2m lengths outside for 5 or 6 years before disposing of them. I was surprised at how well they held up. Im sure they would have done even better if they had been painted.. Not sure of the cost but it should be very inexpensive. Cost of the resin would be the biggest factor.

Common mode RF signals cannot exist on the inner conductor of an
ideal coax feedline and is forced to the outside of the braid by the
laws of physics. The coax has to be less than ideal for common mode to
exist on the inner conductor. But common mode signals don't have to
make it to the coax inner conductor to cause noise problems in a
single-ended unbalanced receiver circuit. A differential amplifier is
often used in control circuits to minimize common-mode problems. A
link-coupled transformer will accomplish much the same function for
amateur circuits.

Lets try the simplest expalnation first. If you are familar with RF
current flowing on the outdside of a coax cable during transmit(often
discussed here) it is the same thing but in reverse.

It seems the size of the loop (I didn't play with loop software yet) is
not critical, but is it possible to say that the lower band you want to
listen, the taller loop you should use?

Hi Sebastien,

Reg Edward's software, that you already have access to, will answer
that far faster than asking here. Reason for that is because of all
the variables that come into play. You can judge for yourself when
you enter them into the program and observe what results are returned.

Hello,

Wish to check out my receiver/antenna on USB signals.

Having a bit of trouble latching on to any.

Are there any USB stations/transmitters that are more or less always
transmitting, and have a reasonably strong signal ?
Live outside of Boston.

For LSB ?

Thanks, and Happy Holidays,
Bob

for usb try between 14150 and 14350 during the day
for lsb try between 7125 and 7300 just about any time, but especially
at night.

I use a 9ft Glen Martin with an A-4S. Its not a DX Killer but you
will work them.

20-25ft up has it limitations on some DX but its doable.

Hi Bob,

Tune into international shortwave broadcasts. Even though they are AM, the have both upper and lower sidebands (yes, I know, didactic). Still and all, it will give you some feel for tuning a signal in. For some receivers that can split a band with narrow IF filtering, this is a good way to DX weak AM signals.

Try WWV at 10 MHz (or any of the other frequecies they transmit on -
multiples of 5 MHz). It is AM so both sidebands are present.

Aviation HF stations are USB. For example, Gander and New York VOLMET
stations on 3485, 6604, 10051, and 13270 MHz

5236. Patch Cable Source ?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-18 15:53:14 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <ieildhlte1@news.eternal-september.org>
Source record: 6235

Hello,

Trying to find a source who actually has in stock a coax patch cable.
Looking for a 6 inch length, SMA M on one end, and a BNC M on the other.

Would be using to provide some flexibility between components.

Coax type probably isn't all that important, as it's a receiving only
application up to 50 MHz, and such a short length.

But a "small" cable O.D. dia would be, to provide some flexibility.

Lots and lots of sources on the web, looked at many, but none seem to
stock anything like this.
As the quantity is small, three pieces perhaps, having someone make a
custom cable doesn't make sense.

Is there a consensus perhaps as to which outfits might have something
like this in stock, and specialize in small quantity "stuff" like this,
that I might have missed ?

Thanks,
B.

i don't see one that short, but this place does custom make them
pretty quick:
http://www.aaarfproducts.com/SMACABLEASSEMBLIES.aspx
maybe just buy a 12" sma-sma and add your own bnc's to get 2 cables.

Pasternack Enterprises has BNC-M to SMA-M adapters, and can make cables
with these end connectors using both RG-58C/U and RG-174. Cost will be
in the $25 to $35 range. I have done business with them before and been
very satisfied.

I should.... But I was better in chemistry :) I should have studied RLC circuits but at this time it was boring... If I had some interest in shortwave listening, I would have been a better student in physics :)

But I should be able to understand :) I think I am going to see if there is any radio club near the place I live. Because I have a lot of questions and English is, as you understood it, not my main spoken language :)

5244. Antenna measurements with 8405

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-20 02:37:30 UTC
From: John - KD5YI <sophi.2@invalid.org>
Message-ID: <iemfhcece1@news.eternal-september.org>
Source record: 6244

Hi -

My frequency of interest is about 434 MHz. I have the following equipment:

HP 8405A vector voltmeter
HP Accessory kit for the above
HP App note AN77-3 (compliments of Wes Stewart)
Fluke 6061A signal generator
Mini-Circuits 40-1000 MHz dual directional coupler.

I'm not sure the info above is really required for this question, but I thought it couldn't hurt.

The question is: I use about an 8-foot piece of coax to go from the output of the directional coupler to the antenna so as to reduce my body and instrument influence. When I follow AN77-3, I do so at the antenna end of the coax. That is, I set up the 8405A with a short at the end of the coax. I figure the coax is only about .8 dB of loss. Is this a valid way of doing the measurement, or must I set up the 8405 with a short on the output of the coupler and characterize the coax and then calculate the answer?

Thanks,
John

Hi Bert:

I don't have any empirical evidence one way or the other. However, knowing a bit about manufacturing... I think that I can reliably say that any antenna design prior to the acquisition would in all likelihood be unchanged from the original design parameters.

The other side of that thinking... a new design, post acquisition would be an unknown.

Just my two cents...

Merry Christmas

I agree that they're unlikely to have changed the design on any of the existing products.

I'm wondering about the quality of the manufactured parts.

Are all the holes in the right place, are the tubes of the correct length, are all the soldered connections actually soldered, etc?

More generally, will the things go together and stay together?

>
> TIA and 73,
>
> -.-. --.-

Almost any height, being as the radials will need to be resonant
to work well. The only difference is the number of radials required
to equal a certain number ground mounted decreases as you
get higher off the ground.
But you have to think in terms of wavelength. What might be fairly
elevated on 10m, which almost be on the ground at 80m.
Say you compare to 120 radials on the ground, which is pretty
much a perfect ground within practical limits.
At 1/8 WL, you might need 60 radials to equal the 120 on the
ground.
At 1/4 WL, you might need 8-10 radials to equal 120 on the
ground.
At 1/2 WL, you can use 3-4 radials to equal 120 on the ground.
On 10m, 1/2 WL is only about 16 feet off the ground.
On 80m, 1/2 WL is about 120 feet off the ground.
In the past I've used a full size quarter wave ground plane on
40m at 36 ft, which is slightly over a 1/4 wave up.
I used four sloping radials. I came to the conclusion that the
system was about equal to a ground mounted system with 60
radials.
Some have speculated that ground planes can be run very low
to the ground with only a few radials, and still be nearly as
efficient as a ground mount with 60-120 radials.
I'm not buying it. There is no free lunch in this regard. :/
If the vertical is elevated, but just barely, count on using
almost as many radials as the ground mount for the same
amount of ground loss. There will be a slight decrease in
the number needed, but not by a large amount.
You will need 1/4 wave radials if elevated. They must be
tuned. Ground mount, it doesn't matter. So you can't

use short .1 WL radials if elevated. Only ground mount can you do that. Elevated, they need to be .25 WL, .75 WL, etc.. They have to be resonant, or otherwise they will be fairly useless.

My experience is as follows:

Hygain - Over the years I've owned a number of their products. Build quality was consistently high. With overall fit, feel and finish what one would expect from an old line firm.

ChushCraft - Much smaller sample base. Build quality was fairly high. With overall fit, feel and finish acceptable, though a bit rough around the edges. Good but not great.

Hi,

does anybody has the exact dimensions of a Versatower 24 m.
I bought a seconhand tower, but I need the exact dimensions and weight for
the truckcompany who'll do the transport.
All plans, schematics are also welcome.

tnx on beforehand,

ON2XXX
Rudi

everything (and more) you always wanted to know about me :

Hello Sébastien,

I think it is a good thing to contact some people locally.

Besides support with the calculation for the inductors and capacitors,
small "construction errors" can degrade performance of a basically
good design significantly.

Be prepared to get many different answers to the same question!

Yesterday evening I experienced strong increase in mains supply
synchronized interference. After some elimination tests, the
"offender" was a new tiny switching plug-in adapter.

I had to use several ferrite cores to reduce the interference from
<3.3 MHz to >15 MHz to an acceptable level. The volume and weight of
the ferrite cores I used exceeds that of the adapter.

About ferrite cores and tapped coils.... I was wondering about
something...

Imagine a tapped coil from a inductance value, let's say "i". what is the
effect of progressively introducing a ferrite core (wand) inside the
tapped coil? Reducing, or increasing "i"?

We were speaking about a Collins receiver. If I read well, it seems to
use this kind of feature. Could be better for experimentation, no?

Sebastien.

p.s. I need to buy something to measure capacitance and inductance (RLC
bridge...).

Here are thy unrestricted signal (upper diagram). It has the three peaks:
http://en.wikipedia.org/wiki/File:Passband_schematic3.png

So in an old radio the same station was in the three places (on the scale)
close to one another.
Am I right?

Nope, you haven't the slightest bit of understanding of what the term
"passband" means so your question is nonsense.

Hello Sébastien,

When you put in a ferrite bar of suitable material, the total inductance will increase. The longer and thicker, the more will be the increase of inductance. The actual increase depends on several factors (length/diameter ratio of coil, and to a lesser extend, ferrite magnetic permeability).

When I put 10*150mm^2 ferrite rods (from old vacuum tube AM/FM radios I believe) into my simple single capacitor preselector, the lowest frequency goes down from 3.4 MHz to 1.1 MHz. The 5 m wire outside wire performs equal w.r.t. my small portable indoor loop on AM BC 1476, 1485 kHz (Spanish stations). Of course, loop positioned and oriented for best reception.

When you look into the technical documentation of ferrite producers/ vendors (Ferroxcube, Fairrite, Amidon, TDK, Epcos, Kitagawa, etc), they will show you a graph that relates inductance change ratio versus

coil dimensions and ferrite permeability. Wrong choice of ferrite material will reduce Q-factor significantly.

The effect on a tapped coil in a circuit depends also on where you start pushing the bar into the coil, as the part of the coil closest to the ferrite bar changes inductance first.

Regarding LCR meter, There are some very nice kits around that measures small inductors and capacitors very well:
http://electronics-diy.com/lc_meter.php gives an example.

Only three? If the modulation is a complex signal (not just a single
sinusoid), you'll get (ideally) a carrier on a single frequency, and
upper and lower sidebands spanning a range of frequencies. Any decent
spectrum analyzer will easily resolve these components.
Communications receivers with narrow bandwidth, sharp cutoff filters
can also resolve them, of course.

And only "in that time"? You still can: there are plenty of AM
stations broadcasting in the 0.5MHz to 30MHz range (and some outside
that). But in 1915, it may well have been easier to analyze the
signal mathematically than with hardware. The hardware may not have
been very common, but certainly the math identities required were
readily available, as was Fourier analysis.

What if both sidebands are NOT "saying the same thing"? Then, for
instance, you can broadcast stereo in a way that receivers mixing the
two sidebands will still receive an acceptable mono signal.

Cheers,
Tom

Hi John,

It's common to calibrate measurements at the end of a piece of line with modern vector network analyzers. The analyzer does much of the work for you: you just put, in sequence, a short, and open and a precision load at the point you want calibrated, and the analyzer does the rest. Obviously loss in the line will reduce the accuracy of measurements: consider the case where the line has infinite attenuation; in that case the signal at the sending end of the line won't change at all for an infinite change in load at the other end of the line. The accuracy degrades monotonically as the line attenuation increases. Unless you're trying to get the absolute best accuracy you can, you probably don't need to worry about 0.8dB loss in the line (1.6dB round trip?). There's an HP ap note (or two or three?) about this. Maybe do a bit of Googling??

If you calibrate with open, short and load, you have the information you need to characterize the line's loss versus frequency and its delay (or phase shift). You don't need to also measure the line

separately. You could view the calibration as having measured the line, in fact.

Cheers,
Tom

Which, in this instance, has squat zilch to do with antennas.

>Only three? If the modulation is a complex signal (not just a single
sinusoid), you'll get (ideally) a carrier on a single frequency, and
upper and lower sidebands spanning a range of frequencies. Any decent
spectrum analyzer will easily resolve these components.

What was in 1915?

>Communications receivers with narrow bandwidth, sharp cutoff filters
can also resolve them, of course.

Have such Author of SSBHistory in 1915?

>And only "in that time"? You still can: there are plenty of AM
stations broadcasting in the 0.5MHz to 30MHz range (and some outside
that). But in 1915, it may well have been easier to analyze the
signal mathematically than with hardware. The hardware may not have
been very common, but certainly the math identities required were
readily available, as was Fourier analysis.

>What if both sidebands are NOT "saying the same thing"? Then, for
instance, you can broadcast stereo in a way that receivers mixing the
two sidebands will still receive an acceptable mono signal.

I am trying to find if that SSB from 1915 were the distance dependent.

FOR DISCUSSION...

RE: YouTube video on this subject at
http://www.youtube.com/watch?v=QWd0nEXFnrE&feature=player_embedded

The comments in italics were posted on another website, which prompted
my five points that follow. Thought they might be of interest here.

It would be interesting to learn if the results and conclusions shown
in the
YouTube video have been confirmed from complete documentation by
an independent test lab.

> but i have another idea that has come out.might be a game changer
> check this out. i have been researching this and it could be the
> breakthrough we need. a broad band antenna, no loading coil needed,
> double the eirp!

Observations from watching the YouTube video...

1. A 1/4-wave monopole was used in the test. A 1/4-wave monopole is
self-resonant, so no loading coil was necessary. However it would be
necessary
for the electrically short monopoles permitted for unlicensed Part 15
AM, and
would still be needed if the FCC changed 15.219(b) to allow a 30'
"ground"
conductor.

2. A 1/4-wave monopole driven against a perfectly conducting ground
plane such
as shown in this video has a peak system gain of about 5.15 dBi. The
video
shows a resonant gain for that monopole system without the sleeve as
"1 dBi"
referenced to the gain of a log periodic antenna.

However by definition the term dBi means decibels with respect to an
isotropic
radiator, and a log periodic antenna definitely is not an isotropic
radiator.
The gain units used in the video are therefore unconventional, and
need further
definition.

3. The relative field radiated by a conventional 1/4-wave vertical
monopole

driven against a perfectly conducting ground plane always is maximum in the
horizontal plane. Such a system radiates virtually 100% of the matched power
applied to its input terminals.

Therefore the peak gain of that antenna system at resonance cannot be improved
by putting a sleeve of any kind on the monopole.

The sleeve may change the shape of the radiation pattern of the system without
the sleeve, though, which could change the field intensity at the location of
the receiving antenna used in the test. This could account for the ~3 dB
improvement shown in their results when using the sleeve.

4. Nothing is shown in the video about the amount of matched power at the
feedpoint with and without the sleeve. If that is not held constant then the
test will be flawed.

5. The VSWR bandwidth of a monopole may be increased simply by using a larger
cross-section conductor of "non-fractal" construction.

That statement is at best misleading, and in some cases incorrect.

In most receivers any *tunable* filter is MUCH MUCH wider than the
bandwidth required to accommodate the bandwidth of the signal transmitted.

The selectivity being produced by one or more *fixed* frequency filters
which are just wide enough to accommodate the bandwidth of the wanted
signal.

Radio waves behaved the same in 1915 as they do now.

The distance to a given field intensity, for the same conditions,
is the same now as it was then.

Well sort of :-)

Before (and during) WWI, anything below 200 meters (over 1.5 mHz) was considered too high in frequency to be useful.

The modulation used has nothing directly to do with the distance a signal
is usefull. That is determined, at a given power and state of the the
ionosphere, mostly by signal to noise ratio which is influenced by the
bandwidth of the modulation method but not by the modulation method itself.

Electomagnetic propagate works the same today as it did in 1915 or even
30,000 BC if anyone had been around with a radio.

You are a babbling idiot.

> Was the video narrated by Phil?

I just watched the video one time and it diddn't sound like Chip to me
not that it matters.
He is comparing to a log periodic as it is non frequency dependent.
When he placed a sleeve over the 1/4 wave it was fed I presume by
capacitive coupling not that it really matters tho capacitive coupling
does help with band extension and constant SWR. He first started with
a circular sheet as a radiator over which he placed a second circular
sheet that is perforated or mesh design.
A mesh design when fed acts like a closed circuit helical where the
current applied takes little interest in the vertical connections so
it to is non frequency dependant the same as the
log style antenna. The mesh current flow is a initial spurt of full
current which then degrades to zero when it get back to the starting
point after at least a single wavelength of travel, not a quarter
wave. Ifg the frequency applied is of many wavelengths it will then
display a near constant SWR over a extended frequency of which there
have been many studies available to confirm. Again if their are enough
wavelengths are present it gets to a equilibrium point of resonance
which includes the overshoot of the applied current. I say resonant
because he is not using fractional wavelength dimensions which are all
floating dimensions where a period (full wave) is not. The overshoot
of applied current increases as much as 5 times, so with the increase
in current it is easily seen that as the current goes so does the
radiation. One could turn around the whole experiment as one of a
radiator inside a Faraday cage which is also used as proof of
reciprocity with respect to radiation from a radiater that is in
equilibrium. Thus it is exactly the same as what I have been proposing
for many years which stems from the Gaussian extension to Maxwells
equation.
I have just completed a similar antenna made as a flat solenoid
without a plunger sometimes referred to as a Meander or pancake
antenne.
It is close to 40 inches dia with a hieght of !/2"
My expectations is that when placed inside a faraday shield, an

example of the Gauss extension it will have a resonance of at least 10 metres down to 160 metres with a SWR less than 3: 1 and an applied impedance of 50 ohms.
I was told that I had a patent on this if I paid publishing cost, acceptance fees and to follow maintanance fees which I declined due to the
high costs.
Best regards to all
Art Unwin

Tonight and yesterday night I played with my experimentation board
(loop...s on my shelves).

I have a 4 loops (square) web :
1 - 8 turns - 1.5 m /side
2 - 3 turns - 1.0m /side
3 - 1 turn - 0.8m /side
4 - 1 turn- 0.65m /side

Each one is inside the other one.

I used the second to be the matching one from the previous, the firts.
The third, to be the mathcing one of the second, etc.

The resonant one gets a variable air capacitor (I change it every time I
need to go higher....).

Very interesting, indeed.

If I understand well, the loop gets the role of inductance and the
capacitor the role of the capacitance... (Lapalisse...). Matching both
gets the best result for a given frequency. I succeed in making apparent
signals that I was not aware of... With this antenna I can tune in the
frequency from 300 KHz to near 7300 KHz... Completely amazing. That's the
first time I can exactly see (thanks to the waterfall information
display) how it does increase, not only the signal, but what's more
important, the signal/noise ratio. I understand now how this is very
important...

What I can see, is that depending on the size of the loop and the
frequency I am monitoring, the variable capacitor may or may not be very
difficult to use, and the bandwidth lack of noise, narrow or wide...
Interesting to see that it is possible to increase the signal without
increasing a lot the signal/noise ratio (better than nothing :). But you
can't play when the signal is too weak.... :)

I am quite happy. It does not tell anything about the antenna efficiency,
but it helps me understand how it works. I get somebody in my family who
is a physics teacher... I need to ask her information about "RLC

oscillators for newbies" to be able to put some rational things upon my experimentations :)

To do next :
- Try to carry out the tiny preselector from Wim (need to find some coper wire... And need to try to recover some old radio parts to play with.... (get some ferrite rods, low value variable capacitors, etc.)
- Try to get some time, and some place, to play with long wires, dipoles and their related matching systems...

Sebastien.

Look at the damped waves: http://en.wikipedia.org/wiki/Damped_wave

The damped waves pulses are simillar to AM (amplitude of oscillation
decreases/increases with time).

The decreasing/increasing may be sharp or gently.

The old damped waves " transmissions have a wide bandwidth".

Was the bandwith the distance dependent?

"Well, it's like this. The story starts in 1915, when mankind discovered
sidebands. Now possessing this superior understanding of the AM signal,
radio scientists began to understand the implications of their discovery.
Soon afterwards, our old friends at Bell Labs, who have discovered
practically everything, developed a method for removing one of the sidebands
of an AM signal but retaining all the essential modulation components. As an
expert of that day supposedly said, "both sidebands are saying the same
thing" (Goodman, 1948). " From:
http://www.hamradiomarket.com/articles/SSBHistory.htm

If in 1915 were no broadcast stations to speak tell us what was with the
first station to speak and when it start transmitting.

The first AM Broadcast station (as opposed to amateur or military) was
in about 1919.

> S*

Damped waves bear little or no similarity to AM, they are essentially pulses with a very different spectral content.

Being pulses the spectral content is wide, tending to infinite, and yes I suppose that the spectrum received by a distant station will vary depending on distance; the lower level spectral lines that are spaced a long way from the fundamental will be lost below the noise as you get further away or the signal gets weaker due to propagation changes. The more side-bands that you loose the slower will be the rise and fall time of the received pulse.

AM is very different the spectrum is much more contained and only 1 side-band is required to replicate the waned signal.

There were no broadcasting stations of any kind in 1915.

The first station that could even remotely be called a broadcasting station
was in 1916 and it broadcasted weather reports in morse code.

The first experimental AM broadcast stations started in 1919 and regular AM
broadcasting started in 1920 when all the spark gap morse transmitters
were shut down.

5295. Balun for a yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-23 21:19:59 UTC
From: VK2KC Gmail <vk2kcjohn@gmail.com>
Message-ID: <if0eej$nd7$1@news.eternal-september.org>
Source record: 6195

Hello,
I am in the process of building a 4 element 2m yagi, centred in 146 Mhz and will be utilising a folded dipole for the driven element.

I came across a commercial folded dipole, fed with coax that had been threaded inside of the driven element. the coax exits through a hole in the centre of the dipole opposite the feed point.
The coax is connected directly to the ends of the dipole, but on closer inspection it is different coax on the feed side to the coax tail, so obviously it is a matching transformer.

Would this be a type of a trombone balun? Assuming it is, then there would be a 1/4 w/l of 75 ohm coax connected to the 50 ohm tail.

Are my assumptions correct?

Has anyone had any experience with this type of matching transformer? I like the look of it as it is certainly tidier that an external 4:1 coax balun.

More or less :-)

I've tended to prefer a gamma match... its far more flexible in terms
of matching and does the balanced to unbalanced conversion as well.

A T match with a 1/2 wave phasing line between the two sides of the T
is what Telrex used to use, very simple to build and rugged.

Several years ago I pulled apart a commercial 160MHz yagi antenna as you describe. It had a very thick folded dipole driven element. The 50 ohm coax tail was feed in at the boom through the inner of one side of the folded dipole & was connected to quarter wave length of coax (120/123 ohm from memory) & the other end was connected to the folded dipole feed point (centre to one side & earth to other).

I pulled it apart to have a look because I was interested in how the very wide bandwidth specification of the antenna was achieved (specification covered whole upper VHF commercial band).

Essentially just a quarter wave length matching section of coax from 50 to 300 ohms.& very thick driven element

Best wishes for Christmas to all on the group.

Might find this Christmas YouTube of interest

The gamma match does not seem to be thought of as working very well at vhf and above. Also it defeats some of the purpose of a balun on a beam. The balun is to keep the current in the antenna balanced which the gamma match will not to. This tends to skew the pattern of the antenna if the current is not ballanced on the antenna elements.

The whole video sounded like a lot of verbal sleight of hand to me.
Its a shame techs and engineers are not secure enough in their
knowledge to recongnize BS when they hear it and report it as such.
"The Emperor's New Antenna".

KCBS, San Francisco, claims to be the direct lineal descendant of
Charles Herrold's broadcasting, which dates from 1910. However,
Herrold's early work involved broadcasting to amateurs, by his own
admission. http://www.charlesherrold.org/KCBS.html, et al.

KCBS and KDKA, Pittsburgh, have been trading claims and counterclaims
for decades. KDKA went on the air in November, 1920 and supporters of
their claim of "First!" say KCBS doesn't date from the Herrold days,
but rather from 1921, when they got their earliest commercial license,
as KQW. I don't claim to be able to settle it here. Oy!

A year earlier PCGG in Holland started broadcasting on November 6, 1919
and is thought to be the first 'real' broadcast station.

On 15th June 1920 Marconi made their first broadcast to the public from
their works in Chelmsford, but it took until 1921 before there were
regular programmes.

Hello Jimmie,

It depends on the design.

In case of a classical transformer, it will be the same, except that the inductance can be divided by 4. Practically this means you can half the number of turns.

For example if the 200 Ohms side have 8 turns, you can reduce this to 4 and this will be the 50 Ohms side. As current increases (with same power), you may use thicker wire, or use two windings in parallel.

In case of a real transmission line transformer, you may need transmission lines with unpractical low characteristic impedance. Maybe you can provide some details about the type of balun you want to make.

Hello Jimmie,

It may not be magic (cheating), but it does not mean that this is the
only solution to get a wide band antenna with reasonable radiation
pattern.

Adding a second (even non-radiating) resonator to a quarter wave whip (or similar structure) does increase the useful bandwidth with a factor 2.5. I used this technique in some commercial UHF designs. "Electrically Small, Superdirective, and Superconducting Antennas" , R.C. Hansen, discusses the resonator technique also.

Adding a third resonator will give slightly more increase of useful bandwidth. Basically it uses the same design techniques as used in broad-banding amplifiers with LC sections. Looking to VSWR versus frequency, it looks like the put the resonator technique in a fractal appearance.

In very wide band applications (> 3:1), you can keep the VSWR within reasonable limits, but a whip-type radiating element may result in a clover radiation pattern. Flared thick structures give better radiation pattern.

> vhf and above.

I've never had any real problems even at 23cms. Certainly non even with
other feed techniques that I've tried.

> Also it defeats some of the purpose of a balun on a beam.

I agree that it wont necessarily prevent common mode currents on the
co-ax.

> The balun is to keep the current in the antenna balanced which the
> gamma match will not to. This tends to skew the pattern of the
> antenna if the current is not balanced on the antenna elements.

I've not really noticed any problems with pattern skew, though I have no
doubt that it occurs. I suspect that it would be more of a issue with
phased arrays.

OT. Merry Christmas to all. (*)

As did Marconi and several others, but they certainly could not be
described as a broadcast station, more like experimental demonstrations.

Again you must differentiate between sporadic demonstrations and the
setting up of a station with scheduled programming, which is what the
discussion is about.

eham sucks
they "moderate" like a communist regime
I was kicked off for trying to resurrect a 1970s model linear that was
made for ham radio but was popular among the CBers of the time. I guess
to be a ham, you must purchase equipment from one of the eham sponsors?

eham is only trolled with a bunch of old dumb hams who have to have their
great grand children or nurse maids turn the computer on for them each
morning so they can go on a destructive rage with everybody young and new
to radio.

HAHAHA Nice example!

Exactly why one should avoid eham!

The people who frequent there are simply too stupid to understand sarcasm
or anything complicated beyond what's on fox news. A disgrace to amateur
radio.

The operative words are "scheduled" and "public" in this context.

There were lots of one off things done before 1919.

This babbling moron has been posting his nonsense for years on the physics and physics.electromagnetic groups.

When I first read his posts years ago I thought his gibberish was because English wasn't his native language but soon came to realize that the issue isn't language, the issue is brain chemistry.

Recently he has moved to the amateur groups, I guess in hopes that the people here won't be as "harsh" as they are in the science groups.

You can give him facts and links all day long, but since he doesn't seem to have more than two synapses that fire properly, he will never understand any response and just continue to babble on.

So there are a few choices to answering his posts:

Don't

Remind him he is a drooling mental case

Respond with some facts that may be of interest to others when he accidently hits on something, such as the history of broadcasting, then remind him he is a drooling mental case

I had thought about the increased current and decided the best way to
compensate for this may be to use a transformer designed for more
power than I had palnned on using As I am only going to be running
100W PEP I figure using a design for 1000W would be more than
sufficent. I had not considered the need for fewer turns. Is this
important?

Do not be angry that you do not know if " did distance affect the
sidebands???? ". It is nothing wrong.
The effect is obvious in light of physics laws. Such obvious that fathers of
the radio did not write about this.
Young people can measure it if it is interesting for them.

distance itself does not affect sidebands.

frequency dependent dispersion in the ionosphere can affect sidebands
and the mark/space tones of rtty differently over short periods
causing differential fading and distortion.

Hello Jimmie,

When you take a transformer type 200 to 50 Ohms balun, the lower frequency limit is determined by the inductance of the 200 Ohms winding (no load connected). This inductance is in parallel with the 200 Ohms source (or load).

When you short-circuit the 50 Ohms side, you will not measure 0 Ohms, but an inductance. This is the leakage inductance due to limited coupling between sec. and prim. winding.

When you use this same balun for a 50 to 12.5 Ohms circuit, the lower frequency limit will decrease. However the upper frequency limit will decrease also, as the leakage inductance is in series with the load.

You can imagine that 150nH (j28 Ohms at 30 MHz) in series with 50 Ohms load is acceptable in many situations, but this same 150nH in series with 12.5 Ohms load may give problems.

Regarding power handling
If you are using your balun with a load with bad VSWR (referenced to 12.5 Ohms), you have to derate power. If the transformer is in a voltage maximum, the core dissipation will increase due to higher flux in it. When the transformer is in a current maximum, wire dissipation will increase.

Best regards,

Wim

One could also consider selective fading.

that's just another name for it... i threw in the big words because
i'm sure that mr.b will look them up out of context and find all sorts
of hilarious ways to recombine them.

http://dj4br.home.t-link.de/ssb3e.htm
I am sure that the all my questions will be explained with the ionosphere.
The first my question was on the frequency doubling.
But yours selective fading means for me "distance itself does affect
sidebands". So you are very helpfull.

For me all names are clear.
Ampere discovered the electrons and give them name "current elements".
Maxwell used "electric particless". But you all admire Heaviside's fluid
(massles and incompressible). Do you see the difference?

Hardly.

At some frequencies the ionosphere is transparent, at some it is reflective,
at some it is absorptive.

And the iononsphere has little to nothing to do with ground wave propagation,
which predominates at AM broadcast frequencies.

But you haven't a clue what any of that means, do you?

> The first my question was on the frequency doubling.
> But yours selective fading means for me "distance itself does affect

Correct conclusion but for totally wrong reasons, much like noticing ice
cream is cold therefor the sky is blue.

> For me all names are clear.

Babble.

> Ampere discovered the electrons and give them name "current elements".

You are wrong as usual.

Richard Laming came up with the concept, the name was by George Johnstone Stoney, the particle itself was identified by Sir John Joseph Thomson.

> Maxwell used "electric particless". But you all admire Heaviside's fluid

From http://en.wikipedia.org/wiki/History_of_radio

<begin quotes>
The question of the 'first' publicly-targeted licensed radio station in the
U.S. has more than one answer and depends on semantics. Settlement of this
'first' question may hang largely upon what constitutes 'regular' programming.

It is commonly attributed to KDKA in Pittsburgh, Pennsylvania, which in
October 1920 received its license and went on the air as the first US
licensed commercial broadcasting station. (Their engineer Frank Conrad had
been broadcasting from his own station since 1916.) Technically, KDKA was
the first of several already-extant stations to receive a 'limited commercial'

license.

On February 17, 1919, station 9XM at the University of Wisconsin in Madison broadcast human speech to the public at large. 9XM was first experimentally licensed in 1914, began regular Morse code transmissions in 1916, and its first music broadcast in 1917. Regularly scheduled broadcasts of voice and music began in January 1921. That station is still on the air today as WHA.

On August 20, 1920, at least two months before KDKA, E.W. Scripps's WBL (now WWJ) in Detroit started broadcasting.

There is the history noted above of Charles David Herrold's radio services (eventually KCBS) going back to 1909.
<end quotes>

So first define "broadcasting".

Mine is a station with a license with a target of the general public and a regular schedule.

Some of you play with the Moon. Are the sidebands the distance dependent?
The distance is huge and the ionosphere is transparent.

But note the start of the quote "<begin quotes>
The question of the 'first' publicly-targeted licensed radio station in
the **U.S.**"

The Dutch beat the US to it!! with regular scheluled programmes from
PCGG starting in November 1919 a year KDKA.

Whilst distance does not affect sidebands per se, it can affect which
sidebands are received, and hence the envelope of a recovered signal.

Consider a pulse train with a spectrum that extends to infinity; the
higher order sidebands when received by a distant station will be below
the noise floor and will not play a part in the recovered pulse train,
so in a way distance has modified the spectrum of the received signal!!

Hello,

Does somebody have experience with ANSOF (www.antennasoftware.com.ar),
especially with planar circuits? Is this a NEC based package?

They say you can use a flat strip as basic element (like in the
"planar" commercial SW packages), though they speak of wire segments
in most other documents on their site. They also mention that you can
simulate wire segments in dielectric or magnetic media. This looks
nice for the relative low price.

Best regards,

Wim

How many times are you going to repeat this nonsense?

Sidebands and distance are not related.

You are a babbling idiot.

Which still makes the year 1919.

Thanks, would it be safe to assume that a transformer designed for 1
to 30 Mhz at 1KW could be used as I have discribed without
modification on 40M. I think the load side should be very close to
12.5. VSWR was 4.1:1 when measured with an Anritsu analyzer a few
weeks ago with no balun attatched. Unfortunately I no longer have
access to that piece of test equipment. The best I can presently
manage is a cheap VSWR meter. Its measurement also agrees with the 4:1
mismatch.

Hello Jimmie,

Very likely yes:

1 kW into 50 Ohms results in 4.5A. Your 100W into 12.5 Ohms results in 2.9A. As your voltage is less, the core loss will also be less. From a power standpoint of view, it is safe to use.

In addition, any phase of load VSWR=4 will not harm the balun at 100W input, as the voltage will not exceed the voltage under 50 Ohms load condition at 1 kW.

As it can be used up to 30 MHz, it is likely that the leakage inductance at 7 MHz will not be a problem, in combination with a 12.5 Ohms load.

Best regards,

Wim

It is when the question is about the first regular broadcast station,
not about one off experiments.

No, it was about the first 'proper' broadcast station. ie not one-off
demonstrations or experiments. ie one with a published and regular
schedule, and a general audience waiting to listen.

Jeff

What is the effect of the inner conductor if I am using the shield only for one of the elements of an antenna? That is, the inner conductor is connected to nothing but the shield is driven.

Thanks,
John

Antenna current is on the outside of the outer conductor. The effect
of the inner conductor is to add a bit of mechanical strength to the
element. In fact, if you use RG-6 with a copper-clad steel inner
conductor, that inner conductor will add considerably to the tensile
strength of the element, and keep it from stretching so much if it's
under tension. You can connect the inner conductor electrically to
the outer at one or both ends and it won't have any effect (unless it
extends significantly beyond the length of the outer conductor).

Cheers,
Tom

Hello Wim...

I haven't use it, but I can steer you to where you can get your questions answered.

Go to www.antennex.com , This site is devoted entirely to antennas and related items. Join the antenna discussion list (no charge) and post your question there.

If there is a group that is more aware of what is going on with antennas, I haven't found it. Everything from PhD professors to ex and current professional antenna designers to "just plain hams" (like me).

All the best

Bill Miller

If you transmit through it make sure you do it at night and have a video
camera on tripod ;-)

Go out and ask 10 or 20 normal people what "broadcast radio" means.

Yes, the arguement is becoming one of semantics, but to most people "broadcast
radio" means radio transmissions for the general public on a regular,
scheduled basis.

Hi Wim...

Sorry. I did not make myself clear. I do not believe there is any useful information on this subject in the antenneX website, nor in Cebik's site. (but there is a TON of other info there!)

From the antenneX website, subscribe to the antenna discussion email list and post your question there. I'll be pretty surprised if you don't get meaningful answers!

All the best,

Bill

be sure NOT to ask in here, since we are obviously not normal
people.... i'm more interested in how mr.B thinks sidebands are
distance dependent than what broadcast radio is.

their description doesn't mention NEC:

"The computer code is based on an Electric Field Integral Equation
(EFIE) expressed in the frequency domain. The current distribution on
metallic structures is computed by solving the EFIE using a full-wave
Method of Moments (MoM) formulation with conformal geometry
decomposition. This means that geometry details are modeled by using
conformal segments, which exactly follow the contour of the structure,
instead of the typical approximation with straight wire segments. "

lots of nice words, and plenty of pretty pictures on their site... but
i wonder how well verified it is.

I believe you are laboring under the false impression that mr.B is able to
think.

Here you are:

Look at the damped waves: http://en.wikipedia.org/wiki/Damped_wave

They are like the AM.

Next look at Mr. Russell's animation:
http://paws.kettering.edu/~drussell/Demos/Solitons/solitons.html

He wrote: "a.. The speed of the wave depends on the height of the wave."

The speed of the disturbance in media is the amplitude dependent - it is the
physics law.

So I do not think. I am sure.
I only want you find out proper evidences. It should be interesting to you.

electromagnetic waves are not solitons. speed of an em wave is not
amplitude dependent, that is a physics law.

Yes. But EM waves are Heaviside's paper waves. In rality are Tesla's waves.
Do not be lazy and look for evidences.

There is no 'evidences' for that. Maxwell's equations describe EM
waves perfectly well, have been verified by experiments for over 100

years, and work fine for me.

Biot-Savart and Heaviside made the very simple model. So simple that it was
choosen to teach the math.
Read at 1825:
http://www.fisica.edu.uy/cursos/electromagnetismo/material/A_Brief_History_of_Electromagne
tism.pdf

It is unfortunate that you do not know the electrDYNAMICS by Ampere and
Maxwell.
It should be interesting to you.
Maxwell did not write "Maxwell's equations".

Maxwell's equations include Ampere's law, Faraday's law, and Gauss's
law... so all the dynamics and statics are included. According to my
history the set of 4 equations was first written by Maxwell in 1863,
though in a different form than they are customarily seen today.

similar, he was referring to an article on solitons which were first
observed on water... but which bear no resemblance to EM waves.

Ah, yes, the website that promoted the CFA while simultaneously warping
electromagnetic theory. But then I guess I just "don't understand".

Thanks, but I'll stick with ARRL pubs and ref books by Kraus, Jasik,
Terman, King & Harrison, et al for trusted, practical info on antennas.
73s,

Because it's entertaining, often thought-provoking and never dull. I have no quarrels with the folks you mention and they can hold whatever views they wish; they are certainly capable of producing workable ham band antennas. The problem is the "procrustean bed" that is often used to "fit" the theory to the antenna design. In the extreme it's the difference between tinkering and hoping for an efficient, practical solution vs. applying good engineering and science in coming up with a viable implementation (which is why I mentioned those reference books in my previous post). Sincerely, and 73s from N4GGO,

Hello Bill,

You did make yourself fully clear to me with your first reply, thanks
for that. If it is/was useful existing SW, I would expect at least
some info on the antennex site, without the need for creating a new
topic.

I expect that at least some users of antennex also follow this NG and
would respond if they know something about the ansof package.
Therefore I didn't started a new topic yet.

Hello John,

OT: There is info on EH, CFA and other fancy antennas on antennex, and
many other places. That doesn't make such places useless. I have dug
through many documents on antennex and there is lot's of useful info.

As with all "information", the difficulty is finding out whether the
"information" is useful for one's special situation. Some of my
favourite books: Kraus, Orfanidis, the services textbook of radio
volume 5, antenna engineering handbook (Johnson).

And he hasn't a clue that solitons require a medium to exist while EM does
not.

To him, an EM wave, a sound wave, a water wave, and a female member of the
Navy in 1944 are all the same thing.

similar, he was referring to an article on solitons which were first
observed on water... but which bear no resemblance to EM waves.

Yes. But it bear resemblance to ELECTRIC waves.

Well, I was there for most of the CFA "saga," and saw no such "promotion."
Instead, I watched the constant stream of challenges by both Jack Stone --
the publisher, and a host of others (including yours truly) that examined
the CFA from all angles and came to the same conclusion: The CFA is/was a
hoax based on the inventors's lack of understanding of EM theory.

All the best,

Bill Miller

Give me the equations for an 'electric wave'.

And you are an idiot for thinking that.

They all share SOME properties, but they are three different things.

>Maxwell's equations include Ampere's law,

It has name "Amperes law". It is Biot-Savart law with the displacement
current added by Maxwell.

>Faraday's law, and Gauss's
law... so all the dynamics and statics are included. According to my
history the set of 4 equations was first written by Maxwell in 1863,
though in a different form than they are customarily seen today.

See: http://en.wikipedia.org/wiki/Maxwell's_equations

"Maxwell's equations are named after the Scottish physicist and
mathematician James Clerk Maxwell, since they are all found in a four-part
paper, On Physical Lines of Force, which he published between 1861 and 1862.
The mathematical form of the Lorentz force law also appeared in this paper."

" (As noted above, this terminology is not common: Modern references to the
term "Maxwell's equations" refer to the Heaviside restatements.)"

In Maxwell's paper were 20 equations to describe this model:
http://en.wikipedia.org/wiki/File:Molecular_Vortex_Model.jpg

There are the cross section of the magnetic lines of force. They rotate but
nothing is flowing along them. The rotations rotate the plane of light
polarisation inside of the solenoid.

In Heaviside's "restatement" something flow along the lines and they do not
rotate.

Take a glance at: http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
Excelent English. Perfect physics.

This should be good...

Tell us what is an "electric wave" that isn't a part of an "elecromagnetic
wave".

Oh goody, you can cut and paste from a web page.

Too bad you don't know what any of what you quoted means.

Pure, babbling, word salad gibberish.

The Moleculare Vortex Model refers to magnetic fields, not electromagnetic
fields and there is no light of any polarizatin inside a solenoid.

not only that but the reference is an article from a magazine
published years before the completed set of Maxwell's equations were
first published. During those years there were many changes in the
understanding of electricity and magnetism and EM waves... not that
the initial publication of Maxwell's equations completely converted
those who had different viewpoints, obviously aetherists and adherents
to other old and disproved theories still exist despite 150 years of
experiments that have failed to damage Maxwell's equations.

Hello, and yes, IIRC to his credit Mr. Stone did publish (later on) Dr.
John Belrose's "mythbusting" of the CFA. Who at antennex was demanding
performance measurements to substantiate the CFA's proponents' claims?
Did the quantity and duration of those CFA articles on the website
confer legitimacy and promotion? Did Mr. Stone transform from believer
to skeptic? I wonder if antennex is at least in part more about
entertainment and tantalizing pseudo-science rather than reality. Like
a certain TV show starring two Roto-Rooter plumbers "ghost hunting" in
their spare(?) time. Hey, if you can't get valid measurements on your
test equipment just substitute melodramatics. 73s,

See at this:
http://en.wikipedia.org/wiki/File:Commercial_Solenoid_Dawes_1920.png

There is shown the magnetic flux (Heaviside). Tell me which physical law
produce it (the hand rule is not a physical law).

Now see at Maxwell's model:
http://en.wikipedia.org/wiki/File:Molecular_Vortex_Model.jpg

There the curent in the solenoid physically rotate the magnetic lines of
force.

So " During those years there were many changes in the understanding of
electricity and magnetism" and the hand rule becomes a physical law.

so you have taken 2 unrelated drawings without the explanatory text to show what?

The 'hand rule' as you call it is not a physical law, it is a convention that is used to easily remember relationships expressed in higher mathematics. There is no magic or physical meaning to it... in fact both 'hand rules' are used depending on how you learned your electronics, as long as you are consistent the provide identical results.

Maxwell model (page 304):
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
"Let the vertical circles V and V represent the molecular vortices of which
the line of magnetic force is the axis. V revolves as the hands of a watch,
and V the opposite way."

"We have thus obtained a point of view from which we may regard the relation
of an electric current to its lines of force as analogous to the relation of
a toothed wheel or rack to wheels which it drives."

>The 'hand rule' as you call it is not a physical law, it is a

results.

But what kind of force cause the magnetic flux?

In Part IV Maxwell wrote:
"Now it seems natural to suppose that all the direct effects of any cause
which is itself of a longitudinal character, must be them- selves
longitudinal, and that the direct effects of a rotatory cause must be
themselves rotatory. A motion of translation along an axis cannot produce a
rotation about' that axis unless it meets with some special mechanism, like
that of a screw, which con- nects a motion in a given direction along the
axis with a rotation in a given direction round it ; and a motion of
rotation, though it may produce tension along the axis, cannot of itself
produce a current in one direction along the axis rather than the other."

Does Heaviside's mechanism in form of the 'hand rule' "works fine for you."
EM is for kids. Are You?

EM is for kids?? i take it that you think EM is too simple and you must have a more complicated theory? if that is so then i understand why you are trying to study ancient research, back then there were many competing theories each with separate complicated descriptions about rotations and forces... all of those were made simple when Maxwell combined the essential 4 equations to describe electromagnetic interactions, add in ohms law and the Lorentz force equation and you have everything necessary to describe EM effects... Sometimes simple is best.

must have a more complicated theory?

EM is is a simple version of Maxwell's model.

> if that is so then i understand
why you are trying to study ancient research, back then there were
many competing theories each with separate complicated descriptions
about rotations and forces... all of those were made simple when
Maxwell

It was Heaviside,

>combined the essential 4 equations to describe electromagnetic
interactions, add in ohms law and the Lorentz force equation and you
have everything necessary to describe EM effects... Sometimes simple
is best.

Maxwell's model and EM by Heaviside are not simple.
The most simple and the best is the gas (electron) analogy. All waves are
the same.

analogies are not theories, nor are any good at making predictions.
being able to predict things is required of theories, they must be
able to predict things that can be tested to either prove or disprove
the theory. an analogy is just a story trying to explain one thing as
if it were something else, this unfortunately doesn't work very well.

Maxwell's equations are very simple, that is what is best about them.
They have taken the absolute simplest set of equations necessary to
describe all electro-magnetic phenomena.

Maxwell wrote 20 equations where were the inertia is and all necessary to
wave propagation in a medium.
They are extremally difficult.

>that is what is best about them.
>They have taken the absolute simplest set of equations necessary to
describe all electro-magnetic phenomena.

The 4 Heaviside equations describe the hydraulic analogy. It is known as EM.
The DC is like the water. The AC of electrons is not.

All babbling gibberish.

You never did address the question of what it is you think an "electric wave"
is.

no, the 4 Maxwell equations are all that is necessary for propagation
in vacuum or other medium... its in there, you just have to learn how
to solve them properly. if you are seeing bigger sets of equations
for em waves then you are reading something that is outdated.

you never did give the equation for an 'electric wave'... please
provide that.

you have a poor search engine, i get 6M hits... and all of them are
either for 'electric field' or 'electromagnetic wave'. provide a
formula or specific reference.

5400. Expectations for 135 foot dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2010-12-31 16:01:13 UTC
From: John Ferrell <jferrell13@triad.rr.com>
Message-ID: <tutrh61ppf1m5frl7fj990vdfe63up0c73@4ax.com>
Source record: 6100

I am helping to install a 135 foot dipole on a hillside for HF activity. The antenna will be at least 45 feet from the ground in any direction. I can believe EZNEC so far as the effects of ground on impedance. but I am at a loss when it comes to considering the patterns on the various bands. The ridge is about 200 feet from the antenna.

This is for a club member who recently upgraded to General Class.

Since the ridge is close to the same height and south of the antenna, I am guessing that the computed charts will be a good representation of the northern half of the antenna. NVIS should not change much. The terrain may work as a reflector for over the pole operation. I am afraid the antenna will be of little use to the south.

I expect we will eventually need to do the best we can with an antenna on the top of the ridge. When the snow melts I will try to climb the ridge for a look-see. It will likely be difficult to install due the dense trees.

Any comments, advice, suggestions etc. are appreciated!
John Ferrell W8CCW

just put it up, hook up a tuner if the radio doesn't have one, and
have fun. you can spend all your time modeling trying to figure out
what it may look like, but if you are limited on how you can install
it you can't really control much anyway. an antenna laying on the
ground works much better than one that is only in your computer!
